EANINGS IN THE FIELD OF THYROID SURGERY

J. W. LINNELL
M.C., M.D. Lond., F.R.C.P.
CONSULTING PHYSICIAN, METROPOLITAN HOSPITAL; LATE CONSULTANT, THYROID CLINIC, NEW END HOSPITAL, LONDON

J. E. PIERCY
F.R.C.S., F.R.C.S.E.
SURGEON SPECIALIST IN CHARGE OF THYROID CLINIC, NEW END HOSPITAL, LONDON

A REMARKABLE quickening of interest in diseases of e thyroid gland has been witnessed in this country ring the last two decades. In it the workers at the ew End thyroid clinic, founded by Sir Thomas Dunhill 1932, have been privileged to play a part; and it is the hope of maintaining the interest which has been roused that we now present the case-records of a few f the 3000 goitre patients whom, between us, we have d under our care at New End and elsewhere. Some, e think, illustrate the drama inherent in thyroid surgery hich appealed so much to the late Cecil Joll, once r colleague; some, we hope, may interest other workers the thyroid field. In spite of our long experience in eating patients with toxic goitre we do not claim any pecial knowledge of the workings of the gland. We re, first and last, clinicians who, knowing its many and omplex relationships with other endocrine glands, ever cease to be surprised by the success achieved simply hrough its subtotal removal. We have seen many undreds of sick people—some of them very sick people —restored to health by operation, and this with a ortality-rate of a fraction of one per cent. We have eliberately adopted the anecdotal method in recording e cases and have omitted irrelevant details likely to rove tiresome. Our comments are mostly based on sonal experience.

THYROID CRISIS FOLLOWING TONSILLECTOMY

A generation ago, in what we call the pioneering days of yroid surgery, one of us saw a girl, aged 18, who presented e classical symptoms and signs of mild Graves's disease. nce the tonsils were large and septic, it was thought best at they should be removed before subtotal thyroidectomy s considered. The patient developed a thyroid crisis on after the operation and died 24 hours later.

Inquiries in various quarters which followed showed at this was not an isolated tragedy; that thyroid isis and death had followed tonsillectomy in other yrotoxic patients and had also followed other operaons, some of a comparatively trivial nature. Ever fterwards he insisted that, whenever in a thyrotoxic atient there was another condition demanding operation, e goitre—save in circumstances of dire necessity— hould be dealt with first. Later this became the unvaryng rule at New End, and F. H. Lahey, chief of the amous *thyroid* clinic in Boston, U.S.A., told us recently n private conversation that there, even now in the days f thiouracil, the same rule obtains—"always the yroidectomy first."

It is generally believed that postoperative thyroid isis only occurs in severely toxic patients. Though is is usually so, there are exceptions. The cause of hyroid crisis we do not know. Joll used to say that he new neither its cause nor its treatment and, contrary o current opinion, held that it was not due to hyrotoxicosis.

MALIGNANT PIGMENTED PAPILLOMATOUS GROWTH OF THYROID, WITH PIGMENTED SATELLITES

In 1935 a woman, aged 40, was transferred from the etropolitan Hospital to New End as probably suffering n a pigmented malignant papillomatous growth of the oid, in view of the fact that a small hard tumour—one everal palpable in the anterior triangles of the neck—which had been removed for biopsy had shown such a structure on section, and the thyroid was, on palpation, hard and nodular. Operation revealed a thyroid infiltrated with darkly pigmented growth, and several pigmented satellites. Practically the whole of the thyroid was removed, together with every satellite that could be found. After the operation wound had healed the affected area was treated with deep X rays. When seen thirteen years later there was no recurrence.

This is the only case of a pigmented malignant neoplasm of the thyroid we have met, though a number of such cases have been published at various times in different parts of the world.

TUBERCULOSIS OF THE THYROID

In 1935 a girl, aged 22, was admitted to New End with what appeared to be an ordinary "primary" toxic goitre. A subtotal thyroidectomy was followed by the expected temporary reactionary rise of temperature, and the patient was discharged some ten days after operation. To our surprise the pathological report, received some time later, described not only thyrotoxic changes in the removed gland tissue but also granulomatous tubercles.

In 1939 a girl, aged 25, was admitted with a medium-sized nodular goitre, definite though not severe thyrotoxic symptoms, and a basal metabolic rate (B.M.R.) of + 40. She was taken to be an ordinary case of moderately toxic nodular goitre; a subtotal thyroidectomy was followed by no complications; and she was discharged ten days later. In her case, too, the pathologist reported granulomatous tubercles in the removed tissue.

In 1938 we saw a very different type of case—a man, aged 26, who had previously been treated in a sanatorium for pulmonary tuberculosis and whose X-ray film showed infiltration of both apices, more extensive on the right side. Tubercle bacilli were present in the sputum, but there was no pyrexia. For two months he had been complaining of huskiness of the voice and pain in the right side of the neck. A hard nodular tumour was felt in the right lobe of the thyroid. After observation we came to the conclusion that we were probably dealing with a case of carcinoma of the thyroid in a patient with pulmonary tuberculosis. At operation a cold abscess was discovered in a deeply placed hard nodular lobe adherent to the cricoid cartilage and showing small tubercles on its exposed surface. The lobe was removed in toto. The reactionary pyrexia was very mild and lasted only forty-eight hours. The pathological report described not only fibrocaseous and granulomatous tuberculosis of the thyroid but also thyrotoxic appearances. The patient was later handed over to the care of the tuberculosis authorities.

Perusal of the published reports reveals an extraordinary divergence of views as to the frequency of tuberculosis of the thyroid in the absence of general tuberculosis. We, for our part, are convinced that it is a rare condition since Joll told us, a short time before he died, that in his 9600 thyroidectomies he had never met a case. It is such cases as these that prove the necessity of a pathological examination of every goitre removed. In addition to these cases of tuberculosis of the thyroid at least 2 cases of unsuspected early cancer have been discovered at New End by this means.

It is interesting to note that a granulomatous infiltration seems capable of causing thyrotoxic changes in the gland.

CEREBRAL EMBOLISM RESULTING FROM PAROXYSMAL AURICULAR FIBRILLATION DUE TO GOITRE WITH NO OVERT SYMPTOMS OF THYROTOXICOSIS

In 1936 a woman, aged 36, with auricular fibrillation and a hemiplegia of recent origin was transferred from another L.C.C. hospital to New End because she had also a large nodular goitre. There was no history of acute rheumatism, and there were no signs of mitral stenosis. Apart from the auricular fibrillation there was no evidence of thyrotoxicosis, and the patient stoutly maintained that she had been in good health until the onset of the hemiplegia. Soon after her admission to New End the cardiac rhythm returned to normal spontaneously. A subtotal thyroidectomy was done, and there had been no further attacks of auricular fibrillation when we had news of her some years later. Unfortunately there had been little improvement in the hemiplegia.

Some 20 years ago a woman, considerably younger than the previous one, came to the casualty department of another hospital in a like condition. By the time she had reached the ward, not only had the fibrillation disappeared but the pulse-rate was below 70. She also insisted that previously she had been in good health. An unsuspected nodular goitre was discovered and a subtotal thyroidectomy done. She was more fortunate than the other woman, for not only was there no return of fibrillation after operation but practically all signs of hemiplegia had gone before she left hospital.

Our clinical experience over many years had long ago convinced us that, at any rate in this country, by the time early middle life is reached, the large majority of patients with goitres are thyrotoxic to some extent. Recently we have surveyed about 1400 case-records of unselected goitre patients at New End and have compared the clinical findings with the pathological. In patient after patient of early middle age or older, in whom there had been no clinical evidence of thyrotoxicosis before operation, definite evidence of thyrotoxic changes was revealed by section of the excised gland. Goitres in which there was no evidence whatever of thyrotoxic change were rare in comparison. We realise that the histological diagnosis of thyrotoxicosis is less accurate than the clinical, but it affords, none the less, very valuable evidence.

It seems certain that an attack of auricular fibrillation is occasionally the first recognisable sign of toxic change in a goitre.

It is of the utmost importance to consider the possible presence of a toxic goitre in any patient with auricular fibrillation the cause of which is not clear.

Auricular fibrillation due to toxic goitre is almost always paroxysmal at first and only later becomes established. This is fortunate, for one can at this stage practically promise a non-recurrence of the attacks after operation.

Embolism is in our experience surprisingly uncommon in paroxysmal fibrillation, though it does occur.

If all nodular goitres, "toxic" and "non-toxic" alike, were operated on without undue delay—as we hold they should be—the incidence of auricular fibrillation would be materially reduced.

NOVEL METHOD OF TREATING FEMORAL EMBOLISM RESULTING FROM AURICULAR FIBRILLATION DUE TO TOXIC GOITRE

In 1937 a woman, aged 65, was admitted to New End with a toxic goitre of many years' standing, auricular fibrillation, and congestive failure. After due preparation a subtotal thyroidectomy was done. Three days after operation an embolus, almost certainly originating in the left auricle, lodged in the right common femoral artery at the origin of the deep femoral artery. There was acute pain in the leg, which became mottled, cold, and pulseless, movement was limited, and sensation to touch was diminished. Pulsation of the femoral artery was felt at the level of Poupart's ligament but not below. Under local anæsthesia an incision was made down to the artery for an embolectomy. Palpation of the embolus resulted, to the surgeon's dismay, in its sudden disappearance. Almost immediately, however, there was a return of pulsation of the popliteal and tibial arteries, with flushing and warmth of the limb, which became free from pain. Movements gradually returned. Three days later an embolus lodged at the same level in the left femoral artery. This time the vessel was exposed and the embolus deliberately broken up with the fingers and milked away. The patient was discharged four weeks later, able to walk strongly and with good pulsation of the tibial arteries. The rhythm of the heart had meanwhile returned to normal spontaneously. When seen recently, twelve years after leaving hospital, the patient was in excellent health.

In 1946 another woman, also aged 65, was admitted to New End in a similar condition. An embolus lodged in the left femoral artery six days after admission, and before operation. The artery was exposed, and, with our previous experience in mind, the embolus was digitally broken up
and milked away, with an immediate change of colou
sensation of warmth in the limb as well as a return of
of the popliteal and tibial arteries. Strange to say, te
later not only did another embolus lodge in the same
but also one lodged in the right femoral artery. The
manœuvre was used as before, with the result that circ
in both legs apparently returned to normal. Ten
later, however, dry gangrene was evident in the
phalanges of the big and second toes of the right
Meanwhile a subtotal thyroidectomy had been
This was followed by a spontaneous disappearance o
auricular fibrillation. When seen sixteen months late
patient was in excellent health, the two affected toes
completely healed after loss of the distal phalanx, an
was walking normally.

DEVELOPMENT OF EXTREME "THYROTROPIC EXOPHTHALMOS" ACCOMPANIED BY RISING BLOO PRESSURE AFTER THYROIDECTOMY

In 1938 a woman, aged 48, was admitted to New
with a goitre of moderate size and toxicity and a histo
paroxysmal auricular fibrillation. There was only a
gestion of exophthalmos at the time of admission, an
blood-pressure was no more than 130/80 mm. Hg. W
not expect any untoward symptoms to follow opera
nor were there any at first, and it was only after three m
that definite exophthalmos, with œdema of the eyelids,
noticed. Thereafter the exophthalmos and an associ
ophthalmoplegia increased rapidly; as did the level of
blood-pressure, a reading taken four months after the oper
registering 200/120. So extreme became the exophtha
and so distressing the pain, photophobia, and lacrima
that the patient was transferred to the Radcliffe Infirm
Oxford. There Sir Hugh Cairns removed the roof of
left orbit, leaving the right untouched, since, in his experi
a sympathetic retrogression of the eye on the opposite
occasionally follows decompression of one orbit. In
present case, however, there was little, if any, diminu
of the exophthalmos on either side. Three months late
view of the patient's increasing misery, the retrobulbar sp
were explored. A curved incision was made through
lower lid of one eye, and by gentle dissection a well-def
prolapsed crescentic indurated pad of fat was remo
The following week a similar pad was removed through
upper lid. The other eye was then dealt with in like man
and the final result was excellent both from a cosmetic
a visual point of view.

This operation has been repeated in 3 other pati
with good results, but cases for operation have to
selected with the greatest care, since excess of orb
fat is not present in all cases of severe exophthalm
The case we have described was one of "thyrotr
exophthalmos," so named because animal experime
suggested that it was caused by the thyrotropic horm
deriving from the anterior lobe of the pituitary gla
Now, however, it seems that in man the part played
the thyrotropic hormone is doubtful, and that it
more likely to be due to a complex disorder of
pituitary-hypothalamic system. Happily, the conditi
is not common. Such thyrotoxic patients as we ha
seen with it have all been only mildly thyrotoxic; th
we understand, is the rule. We have seen it in patien
with hypothyroidism, and in others without eviden
of either thyrotoxicosis or goitre. The exophthalm
and the ophthalmoplegia, which is often associat
with it, usually develop insidiously, but they
develop with remarkable rapidity. Most authoriti
contend that they are generally increased by subto
thyroidectomy; we do not consider that we have se
enough cases to give a worth-while opinion on th
point, especially as we have more than once seen the
develop rapidly in patients awaiting operation. Nor
our experience sufficiently large for us to give an opinio
on the value of endocrine and other medical treatme
of the condition. Recently, however, we have seen
patient who, after a subtotal thyroidectomy for nodula
toxic goitre seven years ago, developed such sever
exophthalmos and ophthalmoplegia that at one tim
orbital decompression was discussed. In spite of the

ing had no treatment, the exophthalmos has practically disappeared, though a certain degree of ophthalmoplegia remains in one eye. This is in accordance with [illegible] le by others that spontaneous [illegible] not complete cure, almost always [illegible] owever, danger to the eyes is very at. Save in the patient whose case we have described length we have not watched a rising blood-pressure ompany an increasing exophthalmos.

ONG REMISSION OF IDIOPATHIC ASTHMA FOLLOWING SUBTOTAL THYROIDECTOMY

In 1939 a woman, aged 44, was transferred from another .C. hospital to New End with the request that a complete yroidectomy should be done in view of her suffering from evere cardiac asthma" as a result of mitral stenosis and rtic incompetence (this was at a time when complete yroidectomy was being advocated by well-known American rdiologists for patients with extreme cardiac failure). It s soon discovered that, though the patient had mitral nosis and aortic *incompetence*, there was no evidence cardiac failure whatever, the attacks being those of opathic asthma, which she had had for years. She d a nodular goitre of moderate size and definite, though ild, toxicity. There were no symptoms whatever of essure on the trachea. Influenced by the trend of current rdiological opinion, we thought it wise to remove the and as completely as possible, for we felt that, quite apart om the cardiotoxic effect it must be exerting, the extreme verity and frequency of the asthmatic attacks warranted ch a procedure, since they could only lead to the early ilure of a heart already badly handicapped. Never did a tient show greater gratitude, for, to our surprise, the tacks of asthma ceased altogether, and when she was seen me years later they had not returned.

This is not an isolated happening. Shortly before e war Dr. J. H. Palmer, of McGill University, told us at a patient of his, with a toxic goitre and asthma, d a like experience; and we have just heard from a tient of ours, a woman of 52, who, after thyroidectomy 1936 for toxic goitre. which, so far as we could see, as causing no symptoms of tracheal pressure. completely lost her asthma until the beginning of this year, hen she had a short-lived relapse.

Unfortunately, thyroidectomy has not proved so ccessful in our other goitre patients with asthma, ven if some have reported considerable alleviation. o explain these successes it will almost certainly be rged that so predominant is the psychological factor the production of asthmatic attacks that any surgical peration can on occasion bring about their cessation —at any rate for a time. Again, it is, we suppose, arguable hat in the cases we have described there was, after all, ressure by the goitre on the trachea or larynx and that his, by adding to the excitement of the bronchial musculature via the vagus, became the deciding factor in the roduction of the attacks in a very nervous asthmatic abject. Unless, however, the predominant psychological ypothesis be invoked, the relief afforded by subtotal hyroidectomy to thyrotoxic patients with no symptoms hatever of tracheal pressure is not easy to explain, specially as many physiologists believe that thyroxin ensitises the sympathetic system. Plausible explanations in plenty can no doubt be adduced, but we ladly leave the problem for others to solve, in the elief that the psychological factor in asthma has been mphasised far too much, and that the full story of the athogeny of the disease has not yet been told.

IRRITATING COUGH AND ILL HEALTH DUE TO UNSUSPECTED TOXIC GOITRE

In 1940 a woman, aged 61, was seen who had had a dry rritating cough for some three years. Associated with it ad been shortness of breath on exertion, languor, easily nduced fatigue, and a considerable loss of weight. Pulmonary tuberculosis had been suspected, but specimen after specimen of such sputum as could be obtained had revealed no tubercle bacilli, and an X-ray film of the chest had shown clear lung fields. She had been seen by a well-known chest specialist, who had been unable to find any abnormality save mild emphysema. A barium swallow had also shown no abnormality. and the radiologist responsible for subsequent films of the chest had been driven finally to a tentative diagnosis of dry bronchiectasis. A "small" goitre had been noted by more than one examiner, but it had been discounted as a possible cause of the symptoms. One glance was sufficient to note that the eyes were definitely staring. and on palpation, low down and deeply placed in the neck, a moderately large nodular goitre, displacing the trachea. could be felt. After a subtotal thyroidectomy the symptoms gradually disappeared.

An irritating cough due to the pressure of a goitre —generally partly retrosternal—on the trachea is not uncommon, and it is well worth bearing this in mind when a patient complains of such a cough. As regards the suspected presence of pulmonary tuberculosis in the present case, it is common experience that the differential diagnosis between pulmonary tuberculosis and thyrotoxicosis is not always easy, since shortness of breath on exertion. languor. easily induced fatigue, and loss of weight are common in both; and, though they were absent in this patient, excessive sweating, especially at night, and slight pyrexia are not rare in thyrotoxicosis. The fact that a persistent cough can occasionally be due to a toxic goitre does not make the differential diagnosis any easier.

UNRECOGNISED THYROID CARCINOMA WITH SECONDARIES IN THE SPINE

Shortly before the war a middle-aged woman was seen by one of us. A few months previously she had been seen by a cardiologist because of pains across the front of the chest and in the back. After a careful examination. which included electrocardiography and screening the chest, he had hesitantly diagnosed coronary disease. Shortly afterwards the patient had begun to complain of pains in the legs also, and she had been handed over to a general physician for investigation in hospital. The physician had concluded that her symptoms were purely hysterical and had sent her home to be under the care of her own doctor. The staring eyes which confronted one on entering her room seemed to demand a palpation of the neck without more ado. An undoubted carcinoma of the thyroid was present; the pains were almost certainly due to secondaries in the spine. The patient was dead in a few weeks.

We record this case for one reason only: goitre is a very common condition and, in spite of a widespread view to the contrary, is in our opinion always a potential danger, for it may at any time become toxic; it may in consequence be responsible for the onset of auricular fibrillation; it may cause pressure symptoms. either by continued growth or by hæmorrhage into its substance; and it may—more commonly than is at present believed in this country—become malignant. Is it too much to ask that students be trained in the future to examine the neck of every patient by inspection and palpation as part of their routine examination. regardless of the presenting symptoms? Thereby, we are convinced, the cause of an appreciable amount of ill health could be discovered. Cardiologists have become increasingly aware of the importance of such an examination. The only criticism of them we make is that some have evidently not learnt to palpate low-lying and deeply placed goitres, since patients have been admitted to New End with auricular fibrillation who have previously attended cardiac clinics without their goitres having been discovered. Since most of these patients have drifted to our clinic by devious paths, we suggest that there may be a still larger number still attending cardiac clinics with unrecognised goitres.

Returning for a moment to carcinoma of the thyroid, it is still not sufficiently recognised that thyrotoxic symptoms and signs are not rarely associated with this condition even if it is doubtful if they are due to it.

TOXIC GOITRE, AURICULAR FIBRILLATION, AND FULL CONGESTIVE FAILURE: SPONTANEOUS RESTORATION OF RHYTHM A FEW HOURS AFTER OPERATION

In 1943 a woman, aged 67, was admitted to New End with a nodular goitre, severe exophthalmos, emaciation, and other signs of severe thyrotoxicosis, as well as established auricular fibrillation and full congestive heart-failure. After five weeks' preparation by rest in bed, digitalis, and, at a later stage, iodine, a subtotal thyroidectomy was done. Twelve hours after operation the rhythm of the heart was regular, and, save for an occasional extrasystole, so remained.

Auricular fibrillation in toxic goitre is commonly attributed to an actual myocardial lesion caused by excessive or disturbed secretion of the thyroid, though some cardiologists contest this view. The present case seems to support their disbelief, for it hardly seems to us possible for a myocardial lesion to be benefited to the degree we have described within twelve hours of operation; rather would one expect it to be worsened temporarily. To us, however, the whole question of auricular fibrillation in toxic goitre is puzzling. It is common for transient fibrillation to develop for the first time soon after operation; it occasionally develops for the first time during operation. On the other hand, it is common for established fibrillation to disappear a week or so after operation and, not rarely, within a few days of it, even if not as soon as in the present case. For the same operation to initiate and stop fibrillation so dramatically is so paradoxical that, in our opinion the matter deserves more consideration than it has so far received.

TOXIC GOITRE, AURICULAR FIBRILLATION, AND EXTREME HEART-FAILURE: RESTORATION OF NORMAL RHYTHM WITH QUINIDINE AFTER OPERATION

A woman, aged 46, was recently seen in desperate straits: she was orthopnœic, deeply cyanosed, and grossly œdematous; the veins of the neck were distended and pulsating; the heart was enlarged; there was auricular fibrillation, and the ventricular rate was practically uncountable; she had an enlarged tender liver, ascites, and hydrothorax. A deeply placed nodular goitre was discovered, and the conclusion reached that the cardiac condition was almost certainly thyrotoxic in origin. On large doses of digitalis and intravenous injections of mersalyl the signs of congestive failure disappeared so rapidly that in a fortnight's time a course of iodine was started. A month after her admission to hospital a subtotal thyroidectomy was done. There was little reaction, and a fortnight later an attempt was made to restore the rhythm with quinidine. In thirty-six hours it was normal, and it has so remained.

We record this case for the following reasons: (1) Thyrotoxic patients with auricular fibrillation and congestive failure are often accounted thenceforward unfit candidates for operation, whereas with careful preparation and a skilled surgeon the mortality-rate is little higher than it is in patients with neither auricular fibrillation nor failure. (2) There seems to be an idea at the moment that thiouracil is absolutely necessary in the preparation of patients with auricular fibrillation for subtotal thyroidectomy, whereas it is our experience that the large majority of patients who develop auricular fibrillation are only mildly thyrotoxic, and, when this is so, iodine is quite sufficient (we reserve thiouracil for very toxic patients). (3) A history of previous congestive failure is regarded by many cardiologists as a contra-indication to the use of quinidine to restore the rhythm in patients with auricular fibrillation. That it is contra-indicated in such circumstances in patients in whom auricular fibrillation complicates mitral stenosis we have no reason to doubt, but this is not so when the auricular fibrillation is the result of thyrotoxicosis. The case we have described is only one of a number of like successful cases we have had under our care. It is understood, of course, that the patients are first digitalised. Most thyrotoxic patients exhibit a remarkable toleran digitalis, so that large doses can be given and cont for long periods not only with impunity but, gen speaking, with excellent results. This is our experi even if it conflicts with the teaching of some well-k cardiologists.

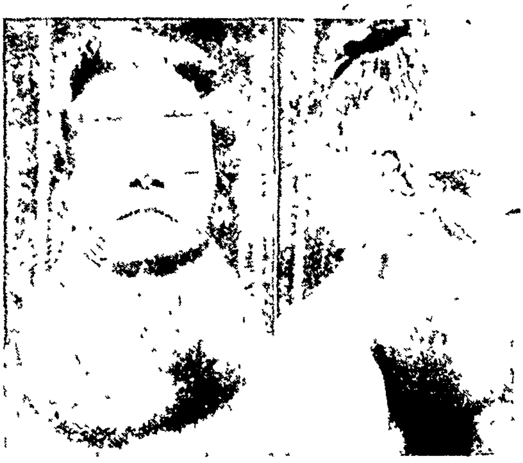

Fig. 1—Large endemic goitre which became toxic.

DOWNWARD EXTENSION OF GOITRE INTO THE POSTERIOR MEDIASTINUM

Early this year an elderly woman was admitted to End with ten years' history of gradually increasing dys on exertion and two years' history of increasing st nocturnal choking sensations, cyanosis, irritating cough, dysphagia. Such was her condition on admission that symptoms or signs of thyrotoxicosis were, if present, impo to elicit. The left lobe of the thyroid was found t enlarged and nodular, and radiography of the chest sh a large mass, partly calcified, in the posterior mediasti The cervical portion of the left lobe of the gland was exp after which the sternum was split to allow removal o prolongation, which extended downwards under the innominate vein to end in a partly calcified mass weig more than 200 g. in the situation revealed by the Pathological examination showed not only conside calcification and old and recent hæmorrhages, but thyrotoxic changes. Convalescence was stormy, but in end the patient made a good recovery.

We have dealt with many large retrosternal prolo tions of goitre. This is only one of several we found extending into the posterior mediastin Though on many occasions all preparations have made to split the sternum for removal of retroste goitres, hardly ever has the need arisen. Almost alw they can be dislocated upwards with the fingers.

ENORMOUS ENDEMIC GOITRE BECOMING TOXIC, LEAD TO AURICULAR FIBRILLATION AND DEATH

In 1936 a woman, aged 49, born and living in the Cotsw was seen with a goitre (fig. 1) so large that she suppo its weight with a shawl knotted over the top of her h The goitre had first been noticed in her teens and caused stridor for 22 years. Latterly it had grown rapi with great increase of stridor and the onset of thyrotoxic Subtotal thyroidectomy was advised, but the patient s bornly refused to consider this because her father had a large goitre and had lived to be 81 and her brother was alive with one as large as hers. The after-history was m as we expected; she soon developed auricular fibrillat which was followed by congestive failure, and she die about a year.

There seems to be an idea abroad that large ende goitres seldom become toxic. This may be the cas some parts of the world and even in some parts of country, but it is not our experience. Recently, instance, a woman from one of the Home Co was seen with a goitre as large as the one descr above, severe thyrotoxicosis, urgent stridor, auri llation, and congestive failure—she also refused ration. Again, over many years a long succession patients with endemic goitres which had become to have been sent to us from one small district in th Wales to New End for operation.

LOCALISED PRETIBIAL MYXŒDEMA FOLLOWING SUBTOTAL THYROIDECTOMY

Eighteen months after a subtotal thyroidectomy for mary toxic goitre. where the diagnosis had been corroated by pathological examination. a woman, aged 42, urned to New End complaining of great weariness. considerb increase in weight, and swelling of the lower legs, on the nt of which a growth of coarse hair had appeared during preceding six months. On clinical examination she was viously mildly myxœdematous, and this was borne out an estimation of the B.M.R. which was −19. It was the s, however. which chiefly interested us. A hard brawny dema was present in both from the feet upwards to just low the knees; anteriorly the skin looked and felt like gskin, and from it grew a thick crop of coarse hairs (fig. 2*a*). X-ray film of the pituitary fossa showed it to be shallow, t there was no evidence of erosion or deformity. The ministration of thyroid strikingly improved her general ndition but did not affect the legs. When the patient s seen eleven years later, all signs of general myxœdema d disappeared, and the legs, which (according to her) d at one time become so unsightly that she had only ntured into the streets after dark, were practically normal appearance save over a small area above each ankle, here the skin was still somewhat thickened, corrugated, d pigmented (fig. 2*b*). The patient had given up taking yroid soon after leaving hospital and had received no atment whatever afterwards.

The disappearance of the general myxœdema did t surprise us, since persistent postoperative myxœdema eding thyroid for a long time is, in our experience, re, the normal metabolic balance being almost always stored through regeneration of the thyroid tissue hich is left. The great improvement in the localised myxœdema" is another matter.

We have seen several other cases of localised pretibial yxœdema, all in patients admitted with thyrotoxicosis, t they were of a milder degree. Two followed subtal thyroidectomy, one the administration of thiouracil, d in the others the condition had developed before peration. In none of them did general myxœdema evelop. There is no known treatment for the condition hich is not a serious one and, as in the case we have escribed, may disappear spontaneously after a time.

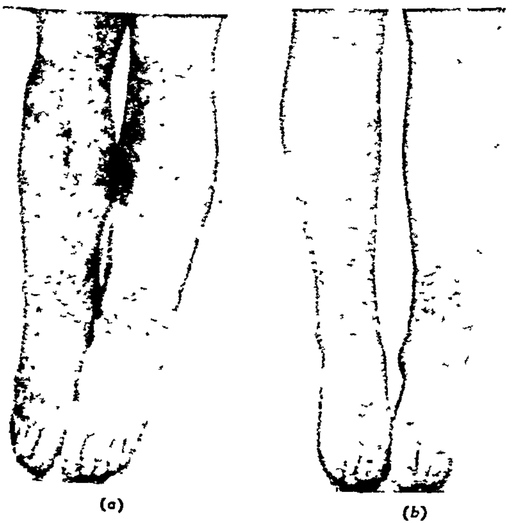

Fig. 2—Localised myxœdema developing after subtotal thyroidectomy: (*a*) eighteen months after thyroidectomy; (*b*) eleven years later.

TETANY ASSOCIATED WITH THIOURACIL THERAPY AND DISAPPEARING AFTER SUBTOTAL THYROIDECTOMY

In 1947 a woman, aged 31, was transferred from another L.C.C. hospital to New End with a history of thyrotoxicosis starting in 1938 after labour. Before transfer she had been treated with thiouracil for a year, during which time she had had several attacks of tetany accompanied by a normal blood-calcium level. After discontinuance of thiouracil and a subtotal thyroidectomy there were no further attacks. There was no question of hysteria so far as we could discover.

Dr. V. C. Medvei has made the interesting suggestion that the tetany was due to hæmorrhage into one or more of the parathyroids caused by the administration of thiouracil, which, as is well known, can cause purpuric hæmorrhage.

AGRANULOCYTOSIS DUE TO THIOURACIL DIAGNOSED AS ACUTE RESPIRATORY DISEASE

We have no wish to discuss here the much debated question of the value of thiouracil in the treatment of toxic goitre—our views have already been published. We wish merely to draw attention to the fact that only recently we have come across two patients with toxic goitre, known by their doctors to be under treatment with thiouracil. who, on their becoming desperately ill and presenting such symptoms as sore throat, pyrexia, and rigors, were sent to hospital. not as cases of agranulocytosis—which was the actual condition—but of acute respiratory disease. With the wide and, we fear, often indiscriminate use of thiouracil by medical practitioners almost from its introduction. we have for long felt certain that the numbers of cases of, and deaths from, agranulocytosis due to it are far larger than are recorded. One of our patients had been ordered one of the sulphonamides, which was only likely to interfere still further with the hæmopoietic system: he died.

RECURRENCES AFTER OPERATION

We naturally have had to deal with recurrences, some in patients operated on at New End, some at other hospitals. They are always a disappointment to patient and surgeon alike, and to the surgeon they are also a cause of considerable anxiety in view of the danger of a second operation to the recurrent laryngeal nerves and parathyroid glands. Recurrences there must be, even in the practice of the most experienced thyroid surgeon merely because the amount of gland tissue he decides to leave can only be based on his past experience, and he has no means of estimating its capacity for regrowth, since this varies with each patient. That the percentage of recurrences, however, can, and should, be materially cut down we have no doubt. The ligation of the inferior thyroid arteries in every case where they are discoverable should alone tend to bring about such a reduction—this was Joll's teaching, and its truth has been amply borne out by our experience, for we can now produce the records of a number of patients in whom the regrowth occurred only on the side where the artery had not been tied.

But there are other means at our disposal conducing to the same end. Both lobes should be exposed in every case, even when a single adenoma appears to be present, for one of the commonest causes of "recurrence" is the continued growth of a lobe unexposed at operation. Over and over again we have seen a lobe apparently normal in situ prove to contain adenomata when thoroughly exposed (such a continued growth is not strictly a recurrence, but it simulates one and is reckoned as one). And we would emphasise the necessity of removing the pyramidal lobe in its entirety in every instance, no matter how small it is. When left it often grows rapidly and can become exceedingly toxic if the original condition was one of toxic goitre. In this connexion, Dunhill, when a colleague of ours, used to say that pyramidal overgrowth in itself is good evidence of toxicity.

We wish to acknowledge our indebtedness to Sir Thomas Dunhill, Mr. Geoffrey Keynes, and the late Mr. Cecil Joll, at one time or another our co-workers at New End, who were responsible for the operations on some of the patients whose case-records we have used in this paper. We also wish to thank Dr. Clark Nicholson, of Moreton-in-Marsh, for the photographs illustrating his case and Dr. Hugh Dunlop for his valuable criticisms.

ACTION OF HETRAZAN ON FILARIASIS AND ONCHOCERCIASIS

F. HAWKING
D.M. Oxfd

WM. LAURIE
D.S.O., M.D. Glasg., T.D.D.
LIEUT.-COLONEL, I.M.S. RETD

From the Filariasis Research Unit of the Medical Research Council, East Africa

'HETRAZAN' (1-diethylcarbamyl-4-methylpiperazine hydrogen dicitrate) is a new compound which has recently been introduced for the treatment of filariasis (Santiago-Stevenson et al. 1947). A previous note has described a study of its mode of action in cotton-rats infected with *Litomosoides carinii* (Hawking et al. 1948); apparently hetrazan acts something like an opsonin, modifying the microfilariæ so that they are seized by fixed phagocytes of the reticulo-endothelial system, which later destroy them. The present note reports the main conclusions reached during preliminary clinical investigations in Tanganyika and Uganda.

Under African conditions the dose schedule must be as simple and short as possible if it is to have any wide application. As a general rule, patients were treated with only one dose per day and treatment was not continued more than seven days.

EFFECT ON MICROFILARIA BANCROFTI

The maximum tolerated dose seemed to be about 20 mg. of the salt per kg. body-weight in one dose daily (see below). Doses as low as 1 mg. per kg. twice daily, or 0·5 mg. per kg. three times daily, removed all or most of the microfilariæ from the blood; but usually doses of 0·2 mg. per kg. twice daily did not completely clear the blood-stream. When bigger doses were given (12–20 mg. per kg. per day) the blood usually became free from microfilariæ in 3 days or less; but rarely a few microfilariæ persisted and stayed at a steady low level of about 1–6 microfilariæ per 60 c.mm. until the end of the observation period (3 months). Large single doses (e.g., 20 mg. per kg.) removed all or most of the microfilariæ from the blood in most of the patients treated; the possibility of mass treatment by such short high-dosage courses is being closely investigated.

Various features of the action of hetrazan upon *Wuchereria bancrofti* in man were compared with the similar features of its action upon *Litomosoides* in cotton-rats; and, when comparison was possible, a close similarity was found. Thus:

(1) When 12 mg. per kg. was given to patients by mouth about 8.30 P.M. (when the microfilarial tide was rising), 60–80% of the microfilariæ had disappeared from the blood at the first time of examination half an hour later. Similarly, when 50 mg. (total) of hetrazan citrate was injected intravenously, so as to cut out the time required for absorption from the alimentary canal, 60% of the microfilariæ in the blood disappeared within 4 minutes.

(2) Microfilariæ of *W. bancrofti* were set up in vitro at 37°C in a medium consisting of serum and Ringer glucose. They lived for several days in contact with hetrazan citrate 200 mg. per 100 ml. or with serum from a patient who had received hetrazan one hour previously. Similar results were obtained with the microfilariæ of *Onchocerca*.

These observations agree with our previous findings about the microfilariæ of *Litomosoides* and show that hetrazan does not have a direct toxic action o microfilariæ nor is it changed by the body into some which does have such an action.

(3) Five patients, who had hydroceles containing r filariæ, were treated with hetrazan, usually at 20 mg. p daily for a week. At the end of this time their night b were free from microfilariæ. Samples of hydrocele fluid taken again and in all cases microfilariæ were still p Hetrazan citrate (about 40 mg. per estimated 100 n hydrocele fluid) was injected into the hydroceles. The day microfilariæ were still present.

These observations support the hypothesis hetrazan acts by sensitising the microfilariæ for ph cytosis by the reticulo-endothelial system, to w microfilariæ in the blood-stream are exposed. however, the microfilariæ are not in contact with phagocytes because they are in a serous cavity, su the hydrocele of a man or the pleura of a cotton they are apparently not destroyed by hetrazan.

EFFECT ON ONCHOCERCA VOLVULUS

(a) *Microfilariæ.*—Owing to allergic reactions dose of hetrazan employed against onchocerciasis much smaller than that used against filariasis, espec in the first 3 days. A common dosage was 50–100 per patient, twice daily, for the first 2 days and t 150–600 mg. twice daily. Under this dosage the s sometimes became negative for microfilariæ after days, but sometimes microfilariæ persisted for m than 10 days in spite of continued treatment. A patients were followed up for 2–3 weeks after tr ment, and some of these relapsed during this per Apparently hetrazan has a marked action on *Mf. volv* but this is less rapid and less permanent than the ac on *Mf. bancrofti*.

(b) *Adult Worms.*—Seven patients were treated 13–27 days with courses of hetrazan at a level of 5–12 per kg. per day, after which nodules were excised examined. In all cases numerous active microfila were still present (indicating the presence of heal adult female worms). Activity of the adult female wo is always difficult to demonstrate even in nodules fr untreated patients; but in three of the above trea cases movement of female worms was seen. In all two cases, active male adults were seen. It is conclu that hetrazan fails to kill many of the adult worms *Onchocerca*.

EFFECT ON PATIENTS

Most of the patients with *W. bancrofti* were treat with hetrazan hydrochloride. This seemed to be bet tolerated (in terms of hetrazan base) than hetraz hydrogen citrate which has since become the standa preparation. In patients with *W. bancrofti* large do of hetrazan hydrochloride (20 mg. per kg. and ov sometimes caused nausea and vomiting, with or witho epigastric pain, especially if given on an empty stomac Occasionally patients complained of tender spots in th groin or scrotum. Otherwise there were no sympton which distressed the patient sufficiently to excite comme or complaint. (The investigation of minor symptoms Africans is often difficult.) This maximum tolerated do of 20 mg. per kg. *once or twice* daily is much higher tha the dose used by previous workers—namely, 2 mg. pe kg. three times daily.

In patients with *Onchocerca*, however, the first dos —even a single dose of 50 mg. hetrazan citrate almost always produced a violent reaction which wa well marked in 16 hours. There was usually swelling œdema and tenderness of the skin, especially of th buttocks and thighs. Sometimes the prepuce, penis, an scrotum were swollen. Intense itching was alwa widespread. Sometimes there was a thick papular ra over the trunk and limbs. The lymph-glands we generally enlarged and tender, especially those of femoral and inguinal groups. There was always pyrexia, ometimes up to 101–102°F. Other symptoms included oreness of the eyes and general aching. These symptoms ubsided after a few days and the patients could then olerate much higher doses—e.g., 12 mg. per kg. daily. The severity of the reaction seemed to be proportionate o the number of microfilariæ initially present in the skin ather than to the level of hetrazan dosage. Apparently he reaction is mostly an allergic one, excited by he breakdown products of microfilariæ injured or estroyed by the drug. This allergic reaction would make hetrazan unpopular if it were used for the mass reatment of onchocerciasis, although it might be quite acceptable if employed for the mass treatment of ilariasis due to *W. bancrofti*. In one patient who had dimness of vision before he was treated for onchocerciasis, he vision deteriorated further during treatment and administration of hetrazan was discontinued.

Much histological material was collected from the patients with onchocerciasis. Full publication will be delayed until this has been cut and examined.

SUMMARY

Hetrazan is very rapid and effective in removing microfilariæ from the blood of patients infected with *Wuchereria bancrofti*. It does not remove microfilariæ from hydroceles and it has no direct toxic action on microfilariæ in vitro. The clinical observations are compatible with the hypothesis that hetrazan acts by modifying the microfilariæ so that they are seized by phagocytes.

Hetrazan removes microfilariæ from the skin in patients with onchocerciasis but apparently it does not kill the adult worms. It is well tolerated by patients with *W. bancrofti* but it provokes violent allergic reactions in patients with onchocerciasis.

Grateful acknowledgments are due to the Directors, and many members, of the Medical Services of Tanganyika and Uganda, without whose kind support this work would not have been possible; and to Mr. D. Garlick for technical assistance.

LOIASIS TREATED WITH HETRAZAN (BANOCIDE)

M.D. Durh., M.R.C.P., D.T.M. & H.
FIRST ASSISTANT, HOSPITAL FOR TROPICAL DISEASES, UNIVERSITY COLLEGE HOSPITAL, LONDON; LECTURER IN CLINICAL TROPICAL MEDICINE, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

This paper records observations at the Hospital for Tropical Diseases, London, on seventeen European patients (eight males and nine females) with loiasis treated with 1-diethylcarbamyl-4-methylpiperazine, the filaricidal drug marketed as 'Hetrazan' (Cyanamid Products Ltd.) and 'Banocide' (Burroughs Wellcome & Co.).

The lengths of residence of the patients in endemic areas of *Loa loa* infection ranged from 1 to 24 years, and the times between last leaving an infected area and coming under the present observation ranged similarly from a few days to 6 years.

In each case, in addition to the clinical assessment, the blood was examined for microfilariæ, both with wet films and with stained thick films, at least three preparations of each being examined where no microfilaria was found; total and differential leucocyte-counts were made; and an intradermal filarial sensitivity test and a filarial complement-fixation test were also performed. These examinations were made before treatment and were repeated at intervals during treatment and subsequently.

BEFORE TREATMENT

Calabar Swellings.—Each patient was subject to calabar swellings, and had been so for periods varying from 6 months to 14 years, the average being 5 years. The frequency of the swellings varied from one every 2 or 3 days in two recently infected persons to one every 4–8 months in a patient who had been infected for 8 years; the average frequency of the swellings was one every 6 weeks.

Microfilariæ were found in only three patients; in the remainder films were repeatedly negative despite undoubted evidence of *Loa loa* infection, including in two patients the presence of worms under the conjunctivæ and in another three patients the appearance of dead worms under the skin during treatment.

Eosinophilia.—The total leucocyte-counts varied from patient to patient from 5200 to 37,000 per c.mm., with an average of 13,080 per c.mm.; the eosinophilia similarly varied from 2 to 59%, with an average of 23%.

Immunology.—A standardised intradermal filarial sensitivity test[1] was positive in each patient, and sera of nine of the seventeen patients gave positive complement-fixation reactions with filarial antigen.

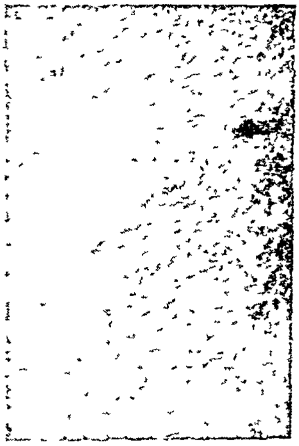

Fig. 1—Dead adult *Loa loa* under skin after treatment.

Diagnostic Criteria.—A diagnosis of loiasis was accepted if microfilariæ of *L. loa* were found or an adult *L. loa* was seen. Failing either of these criteria the diagnosis was accepted if *all* the following conditions were satisfied: (1) the recent history or presence of calabar swellings was beyond doubt; (2) there was an otherwise unexplained eosinophilia of more than 10%; and (3) there was immunological evidence of filarial infection shown by intradermal or complement-fixation tests.

TREATMENT

Dosage.—Owing to limited supplies, each of the first six patients was treated with daily doses of only 2 mg. per kg. of body-weight, but later the daily dose was increased to 4 mg. per kg. in two cases, and then to 6 mg. per kg. for each of the remaining nine patients. The daily dose was divided into three equal portions given by mouth after breakfast, luncheon, and supper. Two patients were treated for 10 days, eight for 14 days, and the remaining seven for 21 days; the total amounts given varied from 1·2 to 10·5 g.

General.—The patients were normally kept in hospital until at least the first week of treatment had been completed, after which, provided they had no toxic symptoms and felt otherwise well, they were treated as outpatients. They were requested to attend the outpatient department at monthly or two-monthly intervals after treatment; in this way one patient has been under observation for 14 months after finishing treatment, one for 12 months, one for 8 months, one for 6 months, two for 3 months, and six for 2 months or less. Questionaries

---

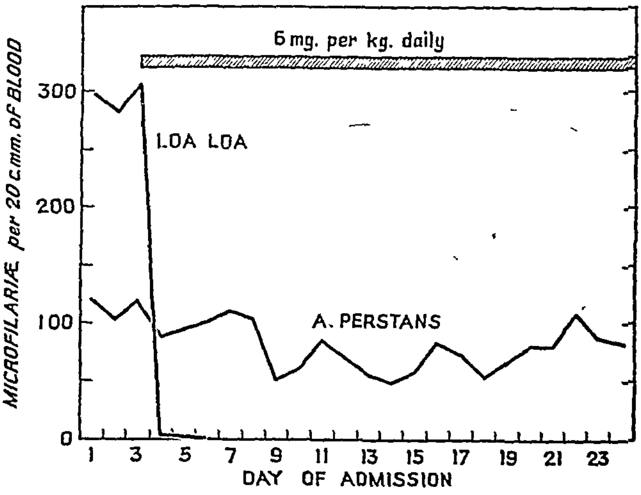

Fig. 2—Disappearance of microfilariæ of *Loa loa* from blood and insensitivity of those of *Acanthocheilonema perstans* under treatment in a patient with a double infection.

were also sent to five patients who went abroad soon after treatment.

IMMEDIATE EFFECTS

Cutaneous Reactions.—On the day after the start of treatment six patients complained of itching, and in three of them the pruritus was accompanied by rashes. In one the rash was morbilliform and diffusely distributed over the trunk, in another it was urticarial and affected only the left arm, and in the third it was papulo-erythematous and affected only the neck and upper chest; the rashes were transitory and lasted only 48 hours. The irritation was more protracted, taking usually 3 or 4 days to disappear, though in one case it lasted 16 days; its intensity seemed less than that of the itching and burning experienced by some patients with onchocerciasis treated with the same drug, and it was alleviated by 'Benadryl' 50 mg. or 'Anthisan' 100 mg. thrice daily. In three patients, one of whom had no other cutaneous reactions to treatment, cutaneous thickenings or nodules appeared; these were about 0·5 cm. in diameter and disappeared in 2 or 3 days. In three further patients cutaneous serpiginous linear swellings appeared, in one patient within 24 hours and in the other two between the 3rd and 4th days from the start of treatment. The appearance, size, and shape of the swellings suggested reactions round adult worms (fig. 1), and in two patients specimens of dead adult *L. loa* were extracted from the swellings; Prof. J. C. Buckley kindly confirmed their identity. Five of the seventeen patients showed no cutaneous reactions during treatment.

Effect on Microfilariæ.—The embryos of *L. loa* rapidly disappeared from the peripheral blood of treated patients. One patient showed a few microfilariæ on the day after the start of treatment but none on the third day, whereas before treatment the average number present at the corresponding time of day was about 300 per 20 c.mm of blood. This patient also had embryos of *Acanthocheilonema perstans* in his blood, and the relative insensitivity of this microfilaria to the drug was clearly demonstrated (fig. 2).

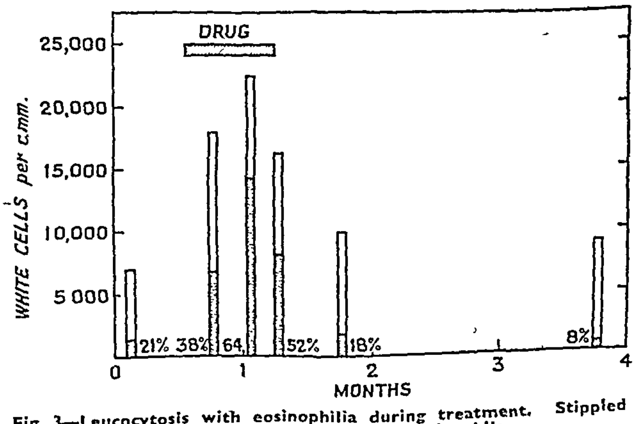

Fig. 3—Leucocytosis with eosinophilia during treatment. Stippled portions of columns represent eosinophils.

Leucocytes.—Many patients showed during treatment a rise in their total leucocyte-count, associated with an increase in the eosinophil percentage (fig. 3).

Temperature.—During treatment three patients showed trivial spikes of temperature. A more interesting effect on temperature was observed in four patients who before treatment were having slight pyrexias accompanied by calabar swellings or visible migrations of worms. Fever is not usually recorded in classical descriptions of loiasis, and it is not clear whether the fever in these patients was accidental or whether the careful observation to which they were being subjected revealed a hitherto unemphasised feature of loiasis. The interesting fact is that in each of the four patients the fever disappeared within 36 hours of the start of treatment (fig. 4).

Nausea without vomiting was encountered in four patients, and lasted 3–5 days after the start of treatment.

Headache.—During treatment four patients complained of headache, which though generally mild tended to persist, lasting from 4 days in one case to the whole duration of the treatment in another.

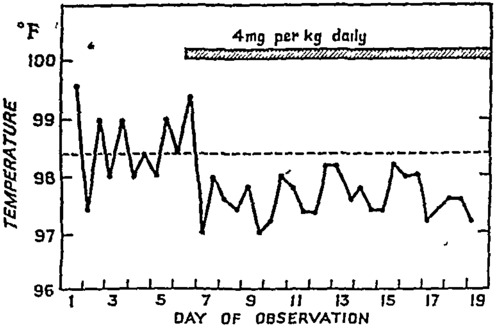

Fig. 4—Fever in an untreated patient and its disappearance und treatment.

LATER EFFECTS

Clinical.—With one exception all the treated patient have remained entirely free from symptoms, and nin have been followed up for 6 or more months after treatment. The one exception had a recurrence of calaba swellings, but this was 3 months after re-entering a endemic area of the disease, so it is possible tha reinfection had occurred. These results are in general agreement with, but seem somewhat better than, thos obtained by Stefanopoulo and Schneider.[2] In most o their patients symptoms, particularly pruritus, recurre though with diminished intensity after an intermissio of only about three weeks following a single course o treatment; to achieve lasting benefit they found i necessary to give 2–4 courses of treatment. Each o their courses lasted only 7–10 days, and it is possible that longer courses have some advantage.

Immunology.—In eight patients the intradermal filarial sensitivity test was repeated 3–5 months after the treatment; the reaction was still positive, as might be expected from its nature. On the other hand, the disappearance of circulating filarial antibody has been demonstrated in several patients. Three months after treatment, five of the nine patients whose sera before treatment gave positive complement-fixation reactions with filarial antigen were retested. In four the reaction had changed from a strong positive to a negative, while in the fifth, though the reaction remained positive, the amount of complement fixed had decreased from 8 to 5 M.H.D. In another patient, re-tested only 2 months after treatment, the reaction had also changed from a strong positive to a weak positive.

---

COMMENT

Neither symptoms nor alterations in total and differential leucocyte-counts were found in two healthy persons to whom the drug was given in doses of 6 mg. per kg. of body-weight daily for 14 days. It seems likely that the reactions in patients with loiasis given the drug are due to the death of the parasites, since embryos disappear from the blood, cutaneous lesions containing dead adult worms are found, calabar swellings and other manifestations of the disease cease, and circulating filarial antibody disappears.

SUMMARY

In loiasis, 1 - diethylcarbamyl - 4 - methylpiperazine brought about disappearance of microfilariæ from the blood and death of adult worms. Cutaneous reactions, headache, nausea, transient fever, and leucocytosis with eosinophilia occurred at times during treatment. In some patients mild fever present before treatment (possibly a hitherto overlooked feature of loiasis) disappeared on treatment.

All the patients except one have remained free from symptoms of loiasis for 1–14 months since treatment; the exception may have been reinfected. Complement-fixation tests showed disappearance of circulating filarial antibody from treated patients.

The findings suggest that the drug is a valuable filaricidal agent in loiasis.

Our thanks are due to the Medical Research Council, Lederle Laboratories Division American Cyanamid Company, and Burroughs Wellcome & Co. for supplies; and to the Wellcome Museum of Medical Science for the photograph.

SEQUELÆ OF MENINGOCOCCAL MENINGITIS IN CHILDREN

J. D. MATTHEWS
M.B. N.Z., M.R.C.P., D.C.H.
LATE HOUSE-PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THOUGH it is widely recognised that chemotherapy has greatly reduced the mortality from meningococcal meningitis in children, it is not so clear from published reports whether or not there is a heavy incidence of sequelæ among the survivors. The fact that some of what may be termed borderline patients who might have died but for modern therapy now survive made it possible that serious sequelæ might even have increased. This study was made to investigate this point.

Between October, 1938, and May, 1948, 50 children with meningococcal meningitis were admitted to the Hospital for Sick Children; 43 were aged 2 years or less, and 29 of these were aged a year or less. There was only 1 child over the age of 5 years. They were all treated with one of the sulphonamides, with or without the addition of antimeningococcal serum or penicillin. The following is the result of an attempted follow-up of these children.

Of the 50 children, 7 (14%) died in hospital of the meningitis; 1 died eleven months later in the Radcliffe Infirmary, Oxford, with pneumonia and bilateral mastoiditis following whooping-cough. At necropsy the only stigmata of the meningitis eleven months before were slight thickening of the arachnoid in the interpeduncular fossa, adhesions and thickening round the base of the brain, and some thickening of the spinal-cord arachnoid.

Of the remaining 42 children, 35 were seen and examined personally; 3 were followed up by letter and a doctor's report obtained where the child was not normal; and 4 could not be traced; but all of them had been seen at various periods after discharge and found to be normal:

Total		*Died*		*Seen*		*Traced*		*Not traced*
50	..	7	..	35	..	4	..	4

PROGNOSIS

The prognosis was worst in the youngest age-group. Thus, of the 29 infants aged a year or less, 6 (21%) died. Of the 14 children aged more than a year and less than 2 years, only 1 (7%) died. There were no deaths among the children aged more than 2 years. The details according to age-group were as follows:

Age (yr.)	*Number*	*Alive*	*Dead*
0–1	29	23 (*79%*)	6 (*21%*)
1–2	14	13 (*93%*)	1 (*7%*)
Over 2	7	7 (*100%*)	0
Over 5	1	1 (*100%*)	0
Total	*50*	43 (*86%*)	7 (*14%*)

It is interesting to compare these figures with those of other groups treated in different ways, including those receiving no specific therapy and those receiving serum alone.

Batten (1915), while on the staff of the hospital at which these patients were treated, found that among infants and young children not given specific therapy the case-mortality was 50%. Slesinger (1933) found a case-mortality of 40% in children under the age of 5 years and treated with serum alone. The introduction of sulphonamide therapy has led to a still lower mortality. Beeson and Westerman (1943) found a mortality of 24% for the same age-group. In the present series, in the children under the age of 5 years there was a case-mortality of 14%. The better figures in the present series may be due to the fact that latterly, in the treatment of the more seriously ill children, early use has been made of intrathecal crystalline penicillin, which has been given at the same time as the systemic administration of one of the sulphonamides. It is interesting to find that in two large surveys, one by Jubb (1943) and the other by Beeson and Westerman (1943), and in a small survey by Banks (1940) the results with sulphonamides alone were better than those with combined treatment with both sulphonamides and serum. The case-mortalities with different methods of treatment were as follows:

Age-group	*Serum* *	*Sulphonamides and serum* †	*Sulphonamides* †	*Present series*
0–1	54%	33%	22%	21%
1–2	10%	13%	18%	7%
0–2	42%	25%	18%	16%
1–5	27%	16%	12%	5%

* Slesinger (1933).
† Jubb (1943).

SEQUELÆ

Of the 42 children who survived in the present series, 4 had sequelæ. In only 1 of these children were the sequelæ so severe as to necessitate admission to a special institution. This child was aged 13 months when he had meningitis. He has hydrocephalus, hemiplegia, and optic atrophy, and is mentally defective and deaf. The other 3 children have deafness as their only disability, 2 of them being almost completely deaf in both ears while the third had bilateral otitis media at the same time as the meningitis and now has impaired hearing in the right ear. Their ages when they had the meningitis were 16 months, 10 months, and 13 months.

Of the 5 children who developed squint during their illness, 3 now have no squint. One has a squint with full range of movements of each eye, and the squint is probably due to the presence of myopia of moderate degree. The other one has a slight inconstant squint; her present age is 16 months and, since she has full range of movements in each eye, it is considered that the squint is probably not the result of the meningitis.

Another child has a pronounced horizontal nystagmus, not noticed before she had meningitis. Examination of the rest of the nervous system reveals no abnormality. She has been seen by the ophthalmic surgeon, who considers that the nystagmus is not causing any disability, is not of ocular origin, and, in view of the family history of nystagmus, is probably familial.

The intervals between the meningitis and the subsequent examinations were as follows:

Interval (yr.)	10	9	8	7	6	5	4	3	2	1	Under 1
No. of cases	2	3	7	1	4	2	0	5	6	5	3

The possibility of late development of sequelæ, such as mental defect or deafness, can be safely excluded in all but the 3 of this series whose examination took place within a year of the original infection. The low incidence of sequelæ with modern treatment compared with that when no specific therapy was available is most noticeable, especially in the infants and younger children. For example, Batten (1915) found that, when no specific treatment was given, 35% of all the cases—i.e., more than half of those surviving—showed sequelæ. The incidence of permanent sequelæ in those receiving serum alone was found by Slesinger (1933) to be 27%. In those treated with sulphonamides the incidence of sequelæ has been much lower. Maddock (1943) found 19% permanent sequelæ. The incidence in this series was 8%.

The commonest permanent complications in this young age-group were said to be blindness, deafness, and mental defect. The incidence of deafness in a large series of cases reviewed by Flexner (1913) was 13% in children receiving no specific therapy and 3·5% in those receiving serum treatment. Slesinger (1933) found the incidence of deafness in those treated with serum alone to be 9%. In the children treated with sulphonamides and reviewed by Jubb (1943) deafness was found in 4%, and in the group surveyed by Degen (1945) deafness was found in 6%. The incidence of deafness in the present series was 8%. Thus it appears that, though specific therapy greatly reduces the incidence of deafness as a complication, deafness is almost equally common in cases treated with serum and with sulphonamides.

In the youngest age-group blindness is said to be the commonest complication, and in the older deafness is more common. That was not found in the present series, where there were 3 children with deafness and only 1 with blindness (the child with deafness, hydrocephalus, hemiplegia, and optic atrophy). The other striking finding in the present series was the low incidence of mental deficiency—only 1 case. There is still a possibility, however, that the last 3 children—those who have been followed up for less than a year—could be backward, though hitherto (they have all been examined at least six months after the meningitis) there are no signs of retardation.

SUMMARY

The present survey shows that (as is already well recognised) adequate chemotherapy greatly reduces the case-mortality in the very young as well as in the older age-groups. What is equally important is that the incidence of serious sequelæ in this age-group was very small. This means that modern treatment of meningococcal meningitis is not just saving life to leave, as a tax on the community and a reflection on modern medicine, a host of defective children.

Thanks are due to members of the medical staff of the Hospital for Sick Children for permission to investigate children under their care.

ISOLATION OF THE KARP STRAIN OF RICKETTSIA TSUTSUGAMUSHI

E. H. DERRICK
M.D. Melb., F.R.A.C.P.

H. E. BROWN

From the Queensland Institute of Medical Research and the Laboratory of Microbiology and Pathology, Brisbane

THE Karp strain of *Rickettsia tsutsugamushi* has been used extensively in experimental work on scrub-typhus (Topping 1945, Fulton and Joyner 1945, Bengtson 1945, 1946, McLimans and Grant 1947, Peterson and Fox 1947, Tullis et al. 1947, Rights and Smadel 1948, &c.), probably because it was the first of those isolated during the 1939–45 war to become generally available for study. Since there have been several conflicting accounts of its origin, it seems advisable to record the circumstances of its isolation (the brief account given by Rights and Smadel (1948) is correct).

An American soldier (Karp) was wounded in the Buna-Gona area of New Guinea, evacuated to Brisbane, and admitted there to the 42nd U.S. Hospital. Soon afterwards he became febrile. On Jan. 15, 1943, a sample of his blood was received in the Laboratory of Microbiology and Pathology of the Queensland Health Department through the courtesy of Major W. C. Merkel. About 1·5 ml. of clot was inoculated intraperitoneally into a guineapig weighing 250 g., and the serum was used for agglutination tests with various organisms. The results of the test with *Proteus* OXK on this and later sera were as follows:

Date		*1 : 20*	*1 : 40*	*1 : 80*	*1 : 160*	*1 : 320*
Jan. 15, 1943	..	–	–	–	–	–
Jan. 30, 1943	..	+++	+++	+++		
Feb. 22, 1943	..	+++	+++	++	+	–

The results with other test organisms were not significant.

Karp recovered from his illness.

The temperature of the inoculated guineapig rose after an incubation period of 10 days, and reached 105·5°F. The guineapig was killed on the third day of fever, and from it other guineapigs were inoculated. The strain was maintained in guineapigs (mostly weighing 200–350 g.), usually by intraperitoneal inoculation of liver-spleen-kidney emulsion, and in this work we had the valued assistance of J. S. Wannan. After thirty-five passages the strain was voluntarily discontinued. The 14 guineapigs of the first nine passages which were not killed for examination and passage all survived the infection. After an incubation period of 5–10 days (average 7·5 days) they underwent a fever lasting 2–8 days (average 5·5 days) with an average maximal temperature of 105·1°F. After nine passages the strain apparently became more adapted to guineapigs, and thereafter the average mortality was about 50%.

Guineapigs killed after several days' fever had a greatly enlarged spleen and rather viscous fluid in the peritoneal cavity. Often there was a fibrinous deposit on the surface of the spleen. Rickettsiæ were usually present in the peritoneal fluid and abundant in the deposit on the spleen. In those guineapigs which died as a result of the infection (the 14th–16th day after inoculation being the most likely period) the pleural cavities were found filled with clear and rather viscous fluid.

The presence of pleural fluid could often be suspected during life by the development of respiratory distress. This symptom commonly appeared about the 14th day and could often be relieved by aspirating the fluid. As much as 17 ml. was removed on the 18th day after inoculation from the left pleural cavity of a guineapig weighing 340 g.; the guineapig's temperature had by then returned to normal for 5 days, and the animal survived the illness. From another guineapig inoculated at the same time and 6 days convalescent, 9·5 ml. of pleural fluid was aspirated, and 4 ml. of this was injected intraperitoneally into each of a pair of guineapigs; these showed no sign of infection.

On three occasions the strain was inoculated into mice and maintained in them for a few passages. Inoculated mice usually died in 6–10 days. Rickettsiæ could be demonstrated readily in the peritoneal fluid after the first passage.

In March, 1943, the strain was sent to Dr. F. M. Burnet, F.R.S., of the Walter and Eliza Hall Institute, Melbourne, after undergoing two passages in guineapigs and three in mice. In July, 1943, material from the nineteenth guineapig passage was given to Commander I. L. V. Norman, U.S.N., for transmission to America. This material apparently met with some misadventure, probably from exhaustion of dry ice during transit, and in the following month a further Karp sample was obtained by Commander Norman from Dr. Burnet. Its arrival at the U.S. Naval Medical Research Institute and subsequent study there are recorded by McLimans et al. (1944). Dissemination of the strain to other laboratories followed, and in this process an active agent was Dr. R. Lewthwaite, who early in 1944 (to use his own words) "scattered typhus strains like confetti at a wedding in America, Britain, and India." His chief "confetti" were the Raub and Seerangayee strains isolated in Malaya in 1932 (Lewthwaite and Savoor 1936) and maintained since, often under considerable difficulties.

A feature of the Karp strain is that it was pathogenic for guineapigs from the first inoculation with human blood. Only a minority of strains of *R. tsutsugamushi* are obviously pathogenic for guineapigs. Lewthwaite and Savoor, for instance, experienced many failures before they established the Seerangayee strain in guineapigs. In this respect the Karp strain may be contrasted with two other strains studied by us in Brisbane in 1940 in conjunction with D. W. Johnson, D. J. W. Smith, and C. L. Greaves but not reported. These strains were isolated by the inoculation of mice with blood obtained from patients with scrub-typhus at Innisfail, North Queensland, by courtesy of Drs. T. J. P. Cotter and R. Hertzberg. The strains were readily maintained in mice for 17 and 13 passages, usually killing the mice in 7–10 days, but attempts to establish them in guineapigs were unsuccessful.

A sequel of the wide use of the Karp strain has been a distressing toll of laboratory infections with it. In Melbourne, this agent was responsible for one tragic death (Burnet 1943). In England there were four laboratory infections during the development of a vaccine intended for use on the Burma front (van den Ende et al. 1946, Fulton 1949), and there were several cases also in America (Bengtson 1945). The Karp strain was probably responsible also for some of the other laboratory infections in which the infecting strain was not specifically mentioned.

SUMMARY

The Karp strain of *Rickettsia tsutsugamushi* was isolated in Brisbane in January, 1943, from an American soldier infected in New Guinea.

Notable features of this strain are its pathogenicity for guineapigs, its extensive use in experimental studies of scrub-typhus, and the number of laboratory infections caused by it.

A NEW CONTRAST MEDIUM FOR HYSTEROSALPINGOGRAPHY

BRYAN WILLIAMS
M.D. Edin., F.R.C.S.E., F.R.C.O.G.
OBSTETRICIAN AND GYNÆCOLOGIST, MIDDLESBROUGH MATERNITY AND GENERAL HOSPITALS

ALTHOUGH iodised oil has been largely used for hysterosalpingography for many years with satisfactory results, some uneasiness has developed about the risk of undesirable sequelæ, particularly because it may produce tissue irritation with serious consequences in the tubes, and also oil embolism, which has proved fatal. To avoid these risks Rubin in 1941 introduced 'Visco-rayopake,' which is a water-miscible substance, and recently Sharman[1] has reported on his findings with a similar contrast medium, 'Rayopake.' Neither substance is generally obtainable in this country.

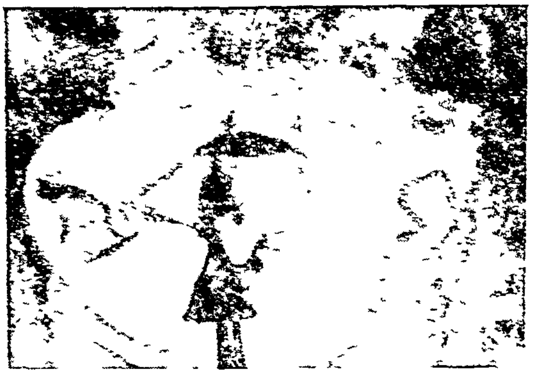
For over a year I have been using a new British contrast medium, 'Viskiosol Six,' which has recently been placed on the market. This contains 50% of diodone in water with 6% of polyvinyl alcohol added to give sufficient viscosity. It is non-irritant and the diodone is rapidly absorbed. Being water-soluble there is no risk of producing oil embolism. No complications have so far arisen with it. Pregnancy is known to have followed its use in at least two patients, and one of these has been safely delivered at term and the other is already beyond the seventh month.

It is usually convenient to take films after the injection of 3, 6, and 9 ml. A cannula of the Provis type has been used, because I do not think it justifiable to injure the cervix with the screw type often recommended. It is essential, however, to keep up firm pressure with the cannula against the cervix with counter-pressure from a volsellum, to prevent the leakage which occurs easily owing to the low viscosity of the solution. A final

---

[1] Sharman, A. *J. Obstet. Gynæc.* 1948, 55, 770.

Fig. 1.



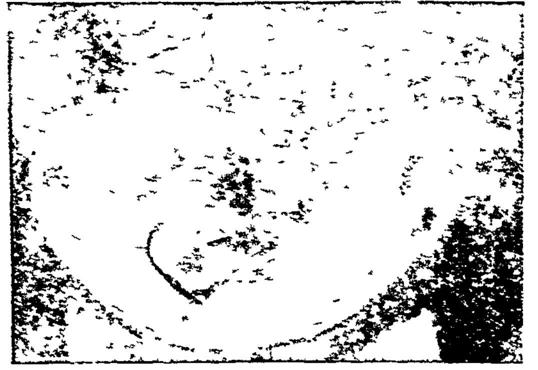


Fig. 2.

film may be taken 5 or 10 minutes after the injection has been finished, to demonstrate the presence of the medium in the pelvic cavity. After this time the shadows become increasingly difficult to recognise in films owing to the rapid absorption of the diodone. Since it is unnecessary to take a further film in 24 hours the use of this new substance offers an added advantage, especially in outpatients.

The shadows of the uterus and tubes are not quite so dense as with iodised oil, and the latter is preferable if it is desired to show deformities of the uterus or filling defects. The appearance of the medium as it passes in a stream laterally from the tubes into the peritoneal cavity also differs from that of the characteristic fall of the globules of iodised oil. Fig. 1 shows the appearances after the injection of 6 ml., and fig. 2 the appearances 5 minutes later.

I am indebted to Messrs. May & Baker Ltd. for supplies of this contrast medium for trial.

COMPLETE HEART-BLOCK ASSOCIATED WITH AMŒBIC HEPATITIS

NORMAL RHYTHM RESTORED WITH EMETINE *

M. D. Rawkins
M.D. Lond.
CLINICAL ASSISTANT, MEDICAL OUTPATIENTS DEPARTMENT

G. L. S. Konstam
M.D. Lond., F.R.C.P.
PHYSICIAN IN CHARGE OF CARDIOGRAPHIC DEPARTMENT

WEST LONDON HOSPITAL

Heart-block associated with amœbiasis is a rarity. In the literature of the last twenty years we have found only three references; and in the three reported cases of auriculoventricular dissociation this complication occurred during the dysenteric phase of the infection. In the course of long-continued diarrhœa other factors may influence the cardiogram; among these should be mentioned anæmia, toxæmia, malnutrition (including thiamine and nicotinic-acid deficiency), peripheral circulatory failure, uræmia, and abnormal blood and tissue chemistry.

Petzetakis (1925) studied polygraphically a European aged 40 who lived in Egypt and had acute amœbic dysentery. Jugular phlebograms showed auriculoventricular dissociation: auricular rate 55–65 per min., ventricular rate 45–50. After four injections of emetine, ventricular extrasystoles appeared, and three days after the ninth injection sinus rhythm was re-established.

Gerbasi (1931) gave very brief cardiac findings in 26 children (mostly wasted infants) with amœbic dysentery. One fatal case, in a child aged 5, showed at times complete and incomplete heart-block (cardiogram not reproduced) and later auricular fibrillation. There were also infants showing prolonged P–R interval (0·18 sec.) and 3 cases of sino-auricular block; also one case of alleged auricular flutter (cardiogram unconvincing) and one with prolonged intraventricular conduction. Response to emetine was scarcely mentioned, and the impression gained is that the circulatory and cardiographic changes were due to dehydration, malnutrition, and anæmia.

Heilig and Visveswar (1943), investigating in Mysore the effects of emetine on the heart, found surprisingly that of 45 cases of amœbic dysentery 34 had abnormal cardiograms on admission. Many of these patients, however, had coexistent chronic malaria, hookworm infestation, and doubtless anæmia and malnutrition. The usual abnormalities were low-voltage or flattened T waves or depression of the S–T interval. In some of these cases improvement in the reco took place after emetine was given. The only case of hear block was in a Mohammedan girl aged 12 years. Befo she received emetine a cardiogram showed complete hear block with ventricular extrasystoles (described in the te as incomplete heart-block). After emetine gr. 6 sinus rhyth was recorded with prolonged P–R interval (0·32 sec.); b after completion of the course of emetine gr. 12, what w probably complete heart-block returned. (Cardiogram str were short and were described as 2 : 1 heart-block.) T general and circulatory condition was said to have be incomparably better after emetine.

In the case of amœbic hepatitis here reported t patient had had no diarrhœa for nine months and w well nourished. The presenting symptoms were pai due to hepatitis, and fainting episodes which proved be Stokes-Adams attacks. Both the hepatitis and t heart-block responded to emetine.

CASE-RECORD

An ex-Army officer, aged 28, was first seen by one of (M. D. R.) on Jan. 1, 1948. He complained of several attac daily of giddiness and faintness lasting one or two minute At no time did he lose consciousness. During the attack which occurred both by day and night, the heart seemed t be missing beats. For a few days he had had lower stern discomfort and pains in the shoulders which increased o breathing. Slight effort dyspnœa had been noticed for year. There was no history of acute rheumatism or diphtheri but he had had scarlet fever at the age of 19, and since the occasional pains in his limbs. In 1942, while serving in th Western Desert, he had had mild jaundice and in the sam year periodic attacks of diarrhœa for which he did not repo sick or receive treatment. Diarrhœa had recurred intermittently, the last occasion being in May, 1947.

He was a well-nourished muscular man. The resting pulse-rate was 40 and regular and rose to 60 after short strenuous exercise. Blood-pressure 145/70 mm. Hg. Heart not enlarged; no murmurs. Liver dullness extended upwards in the mid-axillary line to the fourth interspace. The liver edge could not be felt. A diagnosis of heart-block was made.

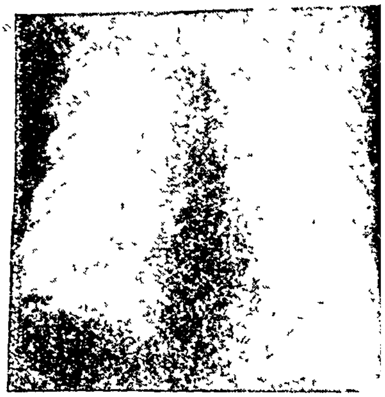

Fig. 2—Postero-anterior radiogram of ches (Jan. 5, 1948) showing right dome of dia phragm raised, with blurred outline mottling at base of right lung; transverse diameter of heart increased to left and right; and prominent pulmonary arc.

During the next three days Stokes-Adams attacks occurred frequently with periods of asystole lasting three to four seconds. He would then feel faint and become pale and sweaty. On Jan. 5, 1948, a cardiogram (fig. 1) showed complete heart-block: auricular rate 88, ventricular rate 31 per min., ventricular rhythm slightly irregular.

X-ray examination (fig. 2) showed that the right dome of the diaphragm was considerably raised; it was immobile, and its outline was blurred. There was also mottling at the base of the right lung, extending up to the right root region. The transverse diameter of the heart was increased to the left and right; the left auricle was not enlarged. The appearances were typical of amœbic hepatitis with inflammatory changes spreading through the diaphragm into the lung above.

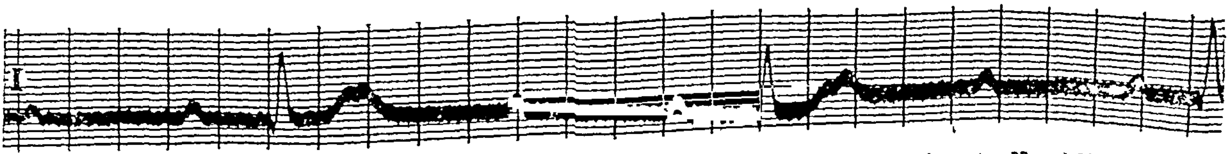

Fig. 1—Electrocardiogram (Jan. 5, 1948), lead I, showing complete heart-block; auricular and ventricular rates 88 and 31 per min.; and ventricular rhythm slightly irregular.

---

* Paper read before the British Cardiac Society May 13, 1948.

Six consecutive stool examinations were negative for *Entamœba histolytica* and sigmoidoscopy showed normal appearances. The white blood-cells numbered 8000 per c.mm.

He was put to bed and daily intramuscular injections of emetine hydrochloride gr. 1 were begun on Jan. 5. After the third injection the lower chest pain disappeared and the pulse-rate increased to 80; it was then quite regular. but next day extrasystoles appeared at every second to fourth beat. The course of emetine (gr. 11) was completed on Jan. 17 and on Jan. 23 a cardiogram (fig. 4) showed restoration of normal rhythm: rate 40 with P–R interval 0·2 sec. Radiography now showed free movement of the diaphragm; the right dome had returned to its normal level and was of regular outline (fig. 3). The heart was more vertical and its size and contour normal.

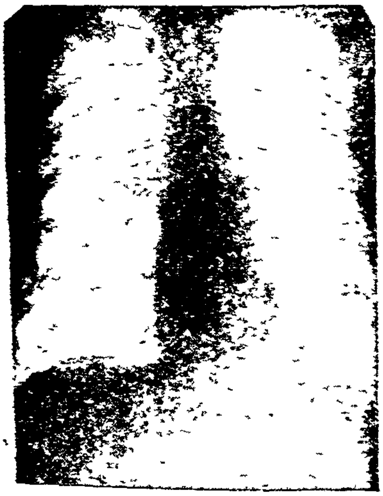

Fig. 3—Postero-anterior radiogram of chest (Jan. 23, 1948) showing right dome of diaphragm now normal in position and regular in outline; size and contour of heart normal; and pulmonary arc still a little prominent.

At this time the patient complained of pains in the jaws, shoulders, and buttocks. The erythrocyte-sedimentation rate was 4 mm. in the first hour (Westergren). The pains gradually subsided during the next four weeks.

A cardiogram on Feb. 2 again showed sinus bradycardia: rate 45. The P–R interval had lengthened to 0·24 sec. but P, R, and T in all the limb leads were of higher voltage. Lead III showed two sino-auricular nodal extrasystoles followed by ventricular escape. By Feb. 23 the pulse had accelerated and a cardiogram (fig. 5) showed normal rhythm, rate 70, with P–R interval 0·2 sec., and no extrasystoles. 'Diodoquin' (di-iodohydroxyquinoline) gr. 3¼ thrice daily was then given for a month. He was apyrexial throughout the illness.

COMMENT

Though final proof of the amœbic origin of the hepatitis was not obtained, the history of recurrent diarrhœa since serving in North Africa, and the rapid response to emetine, left little doubt. The heart-block also disappeared after emetine gr. 3 and the Stokes-Adams attacks ceased shortly after the start of therapy. The decrease in the size of the cardiac shadow during treatment could be attributed to descent of the diaphragm and the restoration of normal cardiac rhythm and rate.

There was no evidence of valvular disease of the heart, but a rheumatic lesion involving the conducting tissues had to be considered in view of the jaw and limb pains which developed during treatment. At that stage, however, the erythrocyte-sedimentation rate was normal, and it seemed more probable that the pains were due to emetine intoxication; the pains disappeared a few weeks later. As to the relation of the amœbic hepatitis to the heart-block one could only speculate as to whether the cardiac lesion was an indirect toxic effect or due to blood-borne amœbic metastases; the latter seemed more likely in view of the rapid response to specific therapy. As the patient had had no diarrhœa for nine months and his nutrition was good, the effects of dehydration and malnutrition could be excluded.

Considering the proximity of the left lobe of the liver to the pericardium, it is strange how rarely the heart is affected in amœbiasis. Possibly cardiographic studies will reveal more such cases in the future.

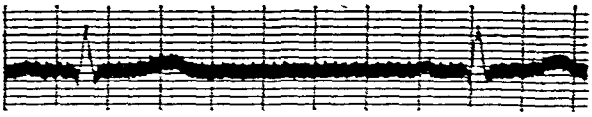

Fig. 4—Electrocardiogram (Jan. 23, 1948), lead I, showing normal rhythm re-established during emetine therapy; sinus bradycardia 40 per min.; and P-R interval 0·2 sec.

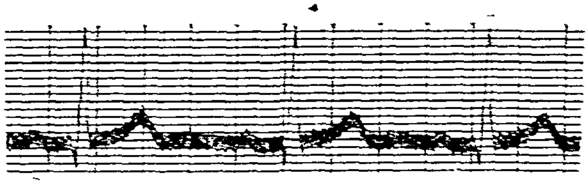

Fig. 5—Electrocardiogram (Feb. 23, 1948), lead II, showing bradycardia superseded by sinus rate of 70 per min.

Extension upwards of an abscess of the left lobe of the liver may cause inflammatory adhesion of the two layers of the pericardium, or rarely the abscess may rupture into the pericardium with rapidly fatal result (Connor 1929).

SUMMARY

A well-nourished man with amœbic hepatitis but with no recent dysentery had complete heart-block. which appeared to respond to emetine. In three previously reported cases of amœbiasis with auriculoventricular dissociation the patients had diarrhœa, thus introducing other possible factors affecting the conducting tissues.

Our thanks are due to Dr. T. Fane Tierney for the X-ray photographs.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Developments in India

At a meeting of the section of epidemiology and State medicine on July 6, Sir Allen Daley, the president, welcomed Dr. K. C. K. E. Raja, director-general of health services, government of India.

Dr. Raja surveyed recent developments in the field of health in India. He took as his starting-point the publication of the Bhore report in 1945. At the end of the war India was in a satisfactory financial position, and there were hopes that a quick start might be made with the extensive public-health programme outlined in the report. The partition of the subcontinent, however, brought with it pressing problems which soon absorbed the government's attention. A vast exchange of population with Pakistan was accompanied by much bloodshed: camps had to be opened for the refugees and displaced persons, and food, clothing, housing, and medical care provided. At one time the largest camp held no less than 300,000 inmates. All the available resources of public health were mobilised to meet these needs, and the medical services were heavily strained. The absence of epidemics during those tense months reflected the stupendous efforts that were made.

It was important, he continued, to understand the existing conditions before judging how effective the public-health programme of the new government was likely to be. In 1944 the death-rate in British India was 24·1 per 1000, and the infant-mortality rate 169, compared with 11·9 and 46 respectively in England and Wales. It was estimated that there were 100 million cases of malaria each year, and 2½ million cases of open tuberculosis with an annual mortality from this cause of half a million. There were about 1 million cases of leprosy, a quarter of which were infectious, and about 37 cases of venereal disease per 1000 of the population.

By contrast, the traditional endemic infections of India—cholera, smallpox, and plague—together accounted for only some 5% of the total deaths. The diet of the people was insufficient and unbalanced, being largely cereal. There was also a great shortage of medical personnel, as shown by the figures of 1·6 doctors and 2·4 hospital beds per 10,000 of the population, and 5000 midwives for the whole country instead of the 100,000 who were needed.

The Bhore Committee recognised that the prime needs were for vast expansion of the health services, and for a general rise in the nutritional standards of the people. They drew up a short-term and a long-term programme. The former, to be spread over ten years, provided for the establishment of a primary health-centre unit for each 40,000 of the population; each primary centre was to include a 30-bed hospital, and to afford a service of home-visiting by doctors and nurses. Twenty-five of these units would be grouped under a secondary health-centre unit, in which there would be a hospital of 200 or 500 beds with special departments. The large unit of public-health administration would be the district health organisation, catering for some 3 million of the population. The long-term programme outlined a more detailed and elaborate framework which could be built on the short-term developments. In 1946 all the provincial governments accepted in principle the Bhore Committee's public-health proposals, which were now beginning to be put into effect.

Meanwhile various government measures had an important bearing on public health. The Employees' State Insurance Act provided cash and medical benefits for sickness and injury. At its inception it covered 2,500,000 people, but it would in time be extended to cover 85% of the population. The Factories Act had been newly amended to promote the health, safety, and welfare of factory workers, and provide for medical attention inside the factories. The age at which children might be employed was raised by law from 12 to 13½ years, and adolescents were prevented from entering hazardous occupations. In addition, steps were being taken to control the drug industry. The anti-tuberculosis campaign was advancing steadily, and an extensive programme of B.C.G. vaccination had been started. The provision of rural tuberculosis centres was being considered.

Turning to the problems of medical education and research, Dr. Raja said that the Bhore Committee's three main proposals in this field had all been accepted in principle. The first of these was the establishment of an All-India Medical Institute; cost, and shortages of building materials and teachers were causing delay, but these difficulties would be overcome. The second was the improvement of selected departments of existing medical colleges. The third was the establishment of special teaching and research centres for the study of various diseases; and malaria and leprosy had been singled out as the first subjects for study at such institutes. In addition, a Council for Postgraduate Education would supervise the training of specialists.

The work of implementing various parts of the health programme had been divided between a number of special committees, some of which had already presented their reports. The upgrading committee was examining hospitals with a view to making them suitable for post-graduate teaching. The vital-statistics committee had proposed the appointment of a registrar-general for India, to be aided by provincial registrars. The first registrar-general had in fact already begun work, and it was hoped that big changes would soon be made in the system of registration in the villages. The leprosy committee had proposed the establishment of a centre at Madras for the study of this disease. The rural health committee had not yet reported. In this field Dr. Raja attached importance to the early establishment of primary health centres, which could show quick results; in some provinces these might be built around the existing anti-malaria dispensaries. Furthermore, an effective anti-malaria campaign could greatly improve the general standard of living in the locality, as had been convincingly shown in Ceylon. Another committee was concerned with the problem of the indigenous systems of medicine; the government of India took its stand firmly in support of scientific medicine, but felt that research into the traditional systems should be stimulated.

Finally, Dr. Raja emphasised that India was participating actively in the work of W.H.O., on whose agencies it had many members. Both W.H.O. and F.A.O. wer helping India a great deal, especially in the fields o malaria, tuberculosis, and children's diseases.

Sir **Bennett Hance** paid a tribute to Dr. Raja's wor as secretary of the Bhore Committee. He welcomed th proposal to establish an All-India Medical Institute which he felt could do for Indian medicine what th Johns Hopkins Institute had done for America medicine.

Sir **George McRobert** hoped that Indian postgraduates working here would not spend their time studyin for higher British qualifications, but would instead gai practical experience in such specialties as thoracic an plastic surgery; the higher degrees of Indian universitie were quite as good as ours. He asked what the government was doing about population control, which seeme to be the most urgent problem of all.

Dr. Raja agreed that fertility was continuing t outstrip mortality. At present a contraceptive programm was out of the question; there were not enough peopl qualified to give contraceptive advice and training there were religious objections, and the consequence of widely diffusing such advice might be undesirable In any event, the result would not show itself for tw generations. The problem was basically that of food-supply. There were 200,000 square miles of cultivabl land which could be used for food production when malaria was controlled. The productivity of the soil was low, but could possibly be increased threefold over th whole country. These measures would more than clos the gap in the food-supply. There were also grea possibilities of hydro-electric development. The solutio lay in improving the resources of the country, and i educating the individual in a sense of responsibility.

New Inventions

APPARATUS FOR INTERMITTENT VENOUS OCCLUSION

Over ten years have elapsed since Collens an Wilensky[1] first reported the results of intermitten venous occlusion in peripheral vascular disease. The based their theoretical considerations of the practica value of the method on the observations of Lewis an Grant,[2] who found that raising the venous pressure i a limb with a tourniquet, followed by release of th pressure, produced vasodilation of the arteries lasting from half to three-quarters of an hour. In 124 cases o peripheral vascular disease Collens and Wilensky showed that treatment by intermittent venous occlusion could relieve pain, heal ulcers, and increase walking capacity. The benefit was apparent in arteriosclerosis, including diabetic peripheral vascular disease and thrombo-angiitis obliterans. These results were confirmed in this country by Brown and Arnott.[3]

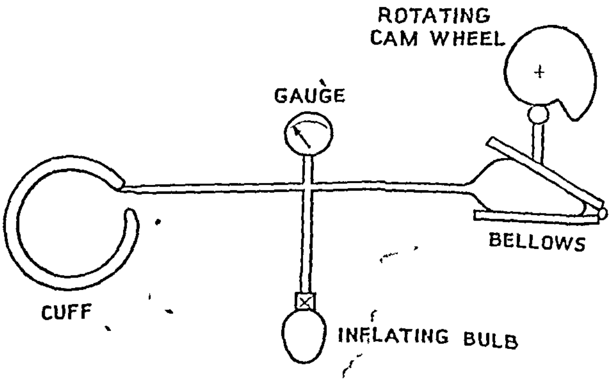

Fig. 1—Principle of apparatus.

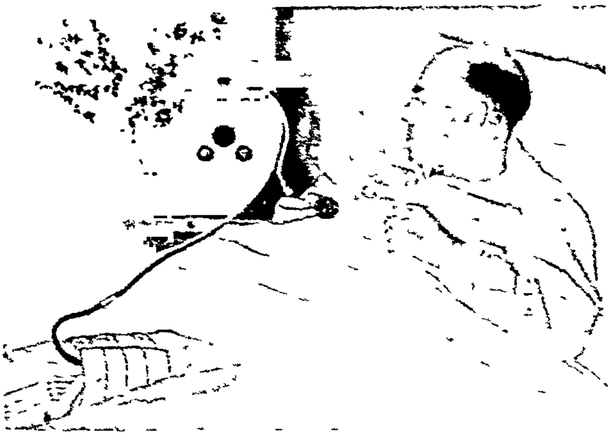

Fig. 2—Apparatus in use ; patient is setting required pressure with bulb.

Somewhat conflicting reports have been received since then about the effect produced by intermittent venous occlusion on the blood-flow through the extremities. But there is little doubt that patients with peripheral vascular disease show symptomatic improvement from this method of treatment, especially where intermittent claudication is present, and walking distances may be increased up to ten times or more.

Further clinical investigation is needed to establish the clinical indications for this form of treatment. It was originally recommended that, where ulceration, sepsis, or gangrene is present, the initial pressure should not exceed 40 mm. Hg, and the period of application an hour at a time, with rest periods of an hour. This should be increased, if the result is favourable, up to 8–10 hours a day with a pressure up to 70 mm. Hg. Where intermittent claudication was present alone, a period of intensive and continuous treatment of 200–300 hours was given, followed by an hour a day when the patient was up and about. There was a tendency to relapse when the treatment was discontinued for a few weeks.

The apparatus used for intermittent venous occlusion by Collens and Wilensky [4] was based on the principle of an air-compressor connected by cam-operated safety and release valves to the occluding cuff round the limb. Brown and Arnott [5] described three types of apparatus: the first two were similar to that designed by Collens and Wilensky, and the third was operated by water pressure. Wilson and Ogston [6] designed a simple and inexpensive apparatus, relying on hydraulic pressure from the household water mains, the intermittent action being brought about by an automatic siphon. Though these machines have given satisfactory service, a simpler and smaller design is more suitable for general home use.

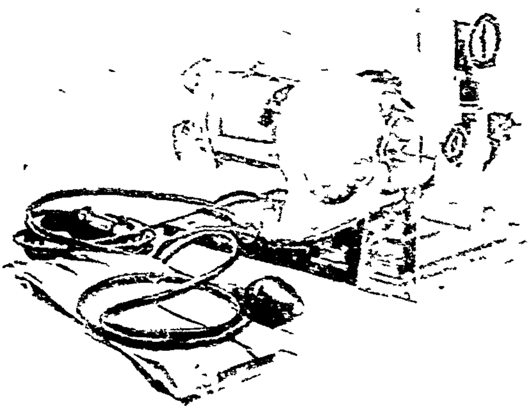

Fig. 3—Apparatus removed from case to show mechanism.

DESCRIPTION OF APPARATUS

The principle of the apparatus is extremely simple, and consists of a slowly turning cam wheel driven through a 7000 : 1 epicyclic reduction gear by a fractional horsepower fan-cooled electric motor. The cam operates a rubber bellows connected by a closed air system to the cuff round the patient's leg; included in the system are a pressure gauge and inflating bulb (fig. 1). The whole is enclosed in a metal case measuring 12½ × 7¼ × 10 inches, in the top of which is a compartment for storing cuff, bulb, and connecting wire (figs. 2 and 3). An indicator window to show when the maximum pressure has been reached, a pressure gauge, and a control switch are mounted on the front panel. On the standard machine the time cycle is fixed at 6 minutes, with 2 minutes' occlusion of the veins and 4 minutes' release (fig. 4): the pressure may be pre-set at 40–80 mm. Hg by the operator. The machine can work either one or two cuffs. Since there are no release valves or air-compressor, the apparatus is practically silent in operation, and its simplicity is such that it can be run for long periods without giving mechanical trouble.

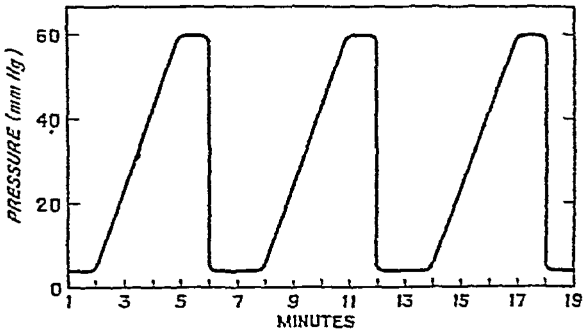

Fig. 4—Pressure curve.

INSTRUCTIONS FOR USE

(1) Plug in to the nearest electric-light point and run the machine until the indicator shows red.

(2) Switch off, and squeeze any residual air out of the bag, after having opened the valve.

(3) Apply the cuff firmly to the leg.

(4) Pump up the cuff with the bulb to the required maximal pressure, close the valve, and turn on the machine, which will continue to run automatically.

The machine will shortly be generally obtainable through Messrs. Down Bros. and Mayer & Phelps Ltd., of 32, New Cavendish Street, London, W.1, to whom I am indebted for much help and criticism.

I wish to thank Prof. Clifford Wilson, Sir Horace Evans, and Dr. William Evans for their advice and encouragement in the development of this apparatus; and also Mr. J. C. Young, of the London Hospital Medical College, and Messrs. Research Engineers Ltd., London, N.1, for their part in producing a design suitable for general distribution and arranging for its manufacture.

“. . . The more a child's development comes about through its interests and affections rather than through moral training, the less sharp are the unavoidable conflicts and their consequences. Most children become over moral without any assistance from the environment, though their demands in this respect tend to become more reasonable as the latency period progresses; and more naughtiness is due to a struggle with an over guilty conscience than to any lack in this.” —Dr. ERNEST JONES. *What is Psycho analysis?* London: Allen & Unwin. 1949.

Reviews of Books

Electrocardiography and Clinical Disorders of the Heart Beat

The late Sir THOMAS LEWIS, C.B.E., M.D., D.SC., F.R.C.P., [illegible] charge of department of clinical [illegible] College Hospital. London: Shaw & Sons. 1949. Pp. 285. 25*s.*

IN this book, completed just before his death in 1945, Sir Thomas Lewis combined his two previous works *Clinical Electrocardiography* and *Clinical Disorders of the Heart Beat*, which first appeared over twenty years ago. The decision to present the two aspects of the subject in one volume is certainly justified, since with the mounting importance of cardiography the two can hardly be considered apart. It is hardly necessary to mention that Sir Thomas was a master both of his subject and of literary style; and though the present volume is very much the same as its predecessors, it still forms an excellent medium for grasping the essentials of cardiac arrhythmias, or as a preliminary to more advanced reading.

Present Conception of Rehabilitation in Tuberculosis

NORVIN C. KIEFER, M.D., medical director, Office of the Surgeon-General, U.S. Public Health Service. New York: National Tuberculosis Association. 1948. Pp. 398. $3.50.

PERUSAL of this handsomely got-up volume suggests that its editor shut himself up in a room for some months and waded through every article that had been written, between 1938 and 1947, about sanatorium and ex-sanatorium patients and their management. There are 1007 references to 670 authors, of whom 350 are quoted in the text. The text consists of quotations, direct and oblique, ripped from their contexts and loosely strung together under fifteen different chapter headings. In the 16th and last chapter the editor attempts the impossible task of straining the broth in which so many cooks have participated, and crystallising out what it is all about. On the dust-wrapper it is said that the volume is "essential to every Sanatorium Director and Tuberculosis Clinician." This is an overstatement.

Schattenseiten der Ulkuschirurgie

Prof. Dr. PAUL HUBER, Vorstand der chirurgischen Abteilung des Kaiserin-Elisabeth-Spitals, Wien. Vienna: Maudrich. 1949. Pp. 91. Sch. 36.

THIS is an account of all the mishaps that can occur after surgical intervention for ulcers of the stomach and duodenum—a unique collection of material. The way to recognise complications, the appropriate treatment, and the likely results are all clearly set out. The experience of the Viennese surgeons is very similar to that of operators elsewhere. Young surgeons will find this monograph of great value and of absorbing interest.

Obstetric Analgesia and Anesthesia

FRANKLIN F. SNYDER, M.D., associate professor of obstetrics and associate professor of anatomy, Harvard Medical School. Philadelphia and London: W. B. Saunders. 1949. Pp. 401. 32*s.* 6*d.*

THE early part of this stimulating book is devoted to respiratory injuries of the child, the second part to the treatment of pain during labour. Professor Snyder describes the physiology and pathology of respiration before birth, discussing intra-uterine pneumonia, atelectasis, and intra-uterine and extra-uterine asphyxia, and showing the part played by analgesic drugs in the production or aggravation of these states. This is a subject of considerable interest, and it is sometimes insufficiently borne in mind that the comfort of the mother, achieved by heavy doses of sedatives or deep anæsthesia, is paid for by respiratory depression in the newborn. The author maintains an acute awareness of this and other causes of respiratory difficulties, and points out that the highest peak of mortality in the entire life-span coincides with the day of birth. The results of various anæsthetic agents on mother and fœtus are set out, and laboratory methods of assessing the effects discussed. This section, well illustrated by charts, photographs, and excellent photomicrographs, includes much of Professor Snyder's original research. Methods of giving various analgesics and anæsthetics are discussed, and barbiturates, inhalation anæsthetics, rectally given analgesics, and local anæsthetics, including spinal and caudal anæsthetics, are compared; but British readers will regret that 'Trilene' is not mentioned. The inhalation anæsthetics, especially nitrous oxide, ethylene, and cyclopropane, are considered to be the best and safest for mother and child. The book is a very wide review of the subject, and will be valued alike by physiologists, pathologists, obstetricians, and anæsthetists.

Vorschlag zu einer leicht durchführbaren Krebsprophylaxe

Dr. RICHARD STOGER, emeritus assistent, der zweiten medizin ischen Universitätsklinik in Wien. Vienna: Maudrich. 1949. Pp. 64. Sch. 15.

DR. Stöger founds his argument on the hypothesis that there is an antagonism between hyperthyroidism and malignant disease. He believes that both clinical experience and animal experiment show that cancer is rare in the presence of excess of thyroid hormone. In his first section he quotes, from a wide selection of published work, the results of using hormones in the *treatment of various malignant tumours.* A second chapter describes a series of animal experiments designed to show the protective effects of thyroid hormone on animals treated with carcinogenic agents. Finally it is suggested that this theory should be applied as a prophylactic measure against cancer in human beings. Unfortunately the reader is left with the impression that the case has been rather overstated and that there is not sufficient proof of benefit to justify the use of the proposed method until it is certain that it will not do more harm than good.

Surgeon's Saga (London: Heinemann Medical Books 1949. Pp. 330. 15*s.*).—Notwithstanding a rather alarming dust-cover this book is an engaging study of one who has carefully analysed his mental problems. The book is somewhat overloaded with the incidents of Mr. Robertson McDouall's career, but his achievements and disappointments are set out straightforwardly and he allows us to watch the development of his philosophy. He reveals himself —once the vagaries of *his student days are past*—as a sensitive, broad-minded man.

Cunningham's Manual of Practical Anatomy, Vols II and III (11th ed. London: Oxford University Press. 1948. Pp. 488 and 513. 21*s.* per vol.).—These two volumes complete the set, the first of which we have reviewed *already.*[1] *Prof. J. C. Brash pays tribute in* his preface to his former teacher, and collaborator in editing "Cunningham," Dr. E. B. Jamieson, now retired. Those who have already devoured the limbs, in volume I, will hardly be content without thorax and abdomen, head, neck, and brain.

Surgery of the Hand (2nd ed. Philadelphia and London: J. B. Lippincott. 1948. Pp. 918. £5).—The first edition of Dr. Sterling Bunnell's great work must be known to most surgeons. If there are any who have not studied it, this is the opportunity to do so. Bunnell is probably best known for his work on cut tendons. The results shown in this book bring new heart to those attempting what is by some considered a hopeless task. Let it be noted that many of his excellent results were achieved a quarter of a century ago. here we truly have a pioneer. Only careful study of his methods, and considerable skill and delicacy of execution can bring like results. He also describes valuable methods of tendon transplantation, to bring new life to palsied hands. Suture of digital nerves has been neglected by many; Bunnell claims excellent results, and has even had good results with suture of main nerves, and with nerve grafting, using the "cable" graft. He also discusses plastic surgery, of which those attempting hand reconstruction need considerable knowledge. Much has been added on metacarpal injuries, on infections, and on tumours; indeed, the book has perhaps become too all-embracing, and is repetitive in places; it is certainly a massive volume. But as a book of reference on the important subject of hand reconstruction no better can be found.

---

Ensuring muscular relaxation in light plane anaesthesia

Reports concerning the value of Eulissin (C10) in producing muscle relaxation during anæsthesia and convulsive therapy appeared in the *Lancet* (1949) *1*, 773 and 775.

Eulissin is free from histamine-like reactions and other undesirable side effects. It can be given in conjunction with all the common anæsthetic agents and it is miscible with solutions of thiopentone.

Eulissin produces adequate muscle relaxation without unduly depressing respiration and has been used in operations of many different types. It can be given just before the peritoneum is closed after laparotomy, and spontaneous normal respiration will be present when the patient is ready to be returned to the ward.

Eulissin is not antagonised by neostigmine. Antilusin (C5) has been used as an antagonist but the effect of Eulissin is sufficiently evanescent to allow controlled or artificial respiration to be the ideal measure of counteracting the paralysis of the respiratory muscles, when it occurs.

Eulissin is supplied in ampoules of 2.5 c.c. each containing 5 mg. of decamethonium iodide, in boxes of 6, 12 and 100 ampoules.

Intermittent Venous Occlusion

Knowledge of obstructive peripheral vascular disease presents a curious paradox. On the one hand there is a wealth of scientific detail concerning the normal and pathological physiology of limb circulation, and on the other almost total ignorance of the causes of thrombo-angiitis obliterans and arteriosclerosis obliterans—the two conditions which cause most non-traumatic obstructive incidents. Indeed diagnosis, in the ætiological sense, is precise only in the embolic group. For treatment a great number of procedures have been evolved with the common aim of minimising tissue anoxæmia by either improving the circulation or diminishing the tissue oxygen requirements; and the multiplicity and differing character of these methods indicates their imperfection. Fortunately, powerful natural mechanisms, such as the vasodilatation of anoxæmia and the growth of collateral arteries, compensate, often with remarkable success, for the effects of arterial obliteration.

One of the many therapeutic methods tried is intermittent venous occlusion. As long ago as 1902 Cushing[1] advocated application of a tourniquet to combat the vasospasm of Raynaud's disease. In 1935 Jordan[2] elevated the affected leg and constricted the thigh with an ordinary sphygmomanometer cuff. Collens and Wilensky,[3] followed soon after by Brown and Arnott,[4] devised apparatus enabling a cuff to be inflated to a pressure of 40–80 mm. Hg in regular cycles of about 2 minutes "on" and 2 minutes "off." It was believed that treatment of this sort practised for several hours daily relieved the resting pain of a seriously ischæmic extremity, minimised intermittent claudication, and possibly accelerated the healing of ischæmic ulcers. Lewis and Grant[5] defined very exactly the increase in blood-flow which follows constriction of the limb for various periods at pressures ranging from complete arterial occlusion down to low levels of venous compression. Intermittent venous occlusion proved most effective at pressures below 80 mm. and often as low as 40 mm. Hg. It seems unlikely that the beneficial effects of compression derive from any transient production of vasodilator metabolites, in view of the high tissue concentration of such substances that must already prevail in the chronically ischæmic limb. Early workers were inclined to attribute the effects to reactive hyperæmia; but further work has not substantiated this theory. Allen and McKechnie[6] observed the digital skin temperature in lower limbs of normal and arterially obliterated patients, taking great care to avoid the action of other factors known to influence temperature; with intermittent-occlusion pressures ranging from 30 to 90 mm. Hg for up to two hours there was no evidence of significant vasodilatation. Veal and McCord,[7] who studied the arteriovenous oxygen differences in limbs subjected to similar treatment, found that complete vascular compression pressures raised the venous oxygen saturation, indicating increased blood-flow, whereas intermittent venous occlusion usually reduced the venous oxygen saturation. This study confirmed and extended the earlier observations of de Takats and others,[8] who found a similar reduction in concentration at intervals of 20–40 minutes after intermittent occlusion was stopped. Although these observations have not brought to light an increase in blood-flow, there remains an unlikely possibility that any vasodilator effect is limited to muscle blood-vessels: this could only be proved by plethysmographic methods. It would be foolish, however, to condemn the procedure because an obvious hypothesis of its mode of action has not been confirmed experimentally. It is easy to imagine other possibilities—for instance, the elevation of capillary pressure that must result from venous occlusion raises the effective filtration-pressure, which in obliterative arterial disease must be abnormally low.

Clinically the procedure has not yet been subjected to carefully controlled trial yielding quantitative data. Nevertheless from many sources comes evidence of its value; the very fact that it is still practised 13 years after its introduction suggests that it has some effect. The treatment has at least the merits that no harm ensues, except in moist gangrene, and patients can treat themselves with a minimum of supervision. Ambulant patients can have the treatment during the night; and provided the apparatus operates silently they soon learn to sleep through the gentle recurrent cycles of compression. For some years a British apparatus has been on sale or hire,[9] and on p. 154 Dr. Shillingford describes a newcomer to the field.

The Value of Hormone Assays

It may be said of the pregnancy test in the year of its coming of age that it has evolved into a most satisfactory youth of which the laboratory has reason to be proud. Six months ago we reviewed[10] the tests which have been introduced since Aschheim and Zondek's[11] basic discovery in 1928 that the increased urinary concentration of chorionic gonadotrophin appearing early in pregnancy and persisting throughout it can be reliably demonstrated by a laboratory method. That account ended with a mention of the two most recent modifications of this group of biological assays—the male-toad test, and the rat ovarian hyperæmia test.

At that time the male-toad test was mainly done on only a single species indigenous to South America, *Bufo arenarum* Hensel, which Galli Mainini[12] had shown would respond to the injection of urine containing pregnancy levels of chorionic gonadotrophin by "spermatogenesis," so that urine collected from the toad's cloaca within 3 hours of injection contains large numbers of spermatozoa. The great deal of work which has since been done on other toads indicates that this response is probably common to all anura. Thus *Bufo marinus*[13]; the common American leopard frog, *Rana pipiens*[14]; the common European edible frog, *R. esculenta*[15 16]; the common North American toad, *B. americanus*[17]; ordinary salientians found in India, such as *B. melanostictus*, *B. stomaticus*, and *R. tigerina*[18]; and finally the common English toad, *B. vulgaris*, on which **Klopper** and **Frank**[19] lately reported in these columns, have all proved as effective as the original South American toad. The rat test depends on the production of ovarian hyperæmia in the immature rat within a few hours of subcutaneous injection of pregnancy urine.[20 21] In the last few months **Albert**[22] has compared the results of this procedure with those of 1000 consecutive Friedman (rabbit) tests. He concludes that the Friedman test will detect concentrations of chorionic gonadotrophin in excess of 500 I.U. per 24-hour urine specimen, whereas the rat test is only half as sensitive and so may give "false negatives" in very early pregnancy; on the other hand, the rat test is likely to become negative before the Friedman test after abortion or fœtal death. **Zondek** and **Sulman**[23] have suggested that only some strains of rats, such as those used in Jerusalem and at the Mayo Clinic, will respond with ovarian hyperæmia, but A. C. **Crooke**, in the discussion on their paper, indicated that the rats he used at the London Hospital responded satisfactorily. Provided it is first established that the rats maintained for experimental purposes in the individual laboratory are sensitive, this is undoubtedly a simple and useful test. Both these tests, therefore, comply with the four criteria essential for the ideal pregnancy test—reliability, convenience, simplicity, and speed—and we may add a fifth criterion which they also fulfil: cheapness. Male toads are inexpensive, easy to keep, and may be used repeatedly; the technique of the test is almost fool-proof; the results are remarkably specific and can be reported to the clinician on the same day as the urine is received—in fact, it might be possible for the test to be performed actually in the outpatient clinic. The rat test might be even more convenient in a laboratory which has access to a large animal-house with a constant and plentiful supply of litters of young rats.

A very different picture is presented when one turns to the clinical value of pregnanediol estimations, which was discussed, perhaps prematurely and at too great a length, at the British Congress of Obstetrics and Gynæcology (see p. 164). As a pregnancy test, it was generally agreed that these estimations fulfilled none of the criteria mentioned above, and as a prognostic test for threatened abortion, or as a test to determine whether a series of repeated abortions are associated with progesterone deficiency, they had proved decidedly equivocal. Indeed, at the moment, the limited clinical usefulness of this highly technical, laborious, and specialised procedure scarcely seems to justify its further serious consideration. But there is much of interest and value to be learnt from a continued and intensified study of this urinary steroid. It is, for instance, already yielding, as Prof. **Marrian** hinted, novel conceptions concerning the metabolism and the effects of exogenous administration of progesterone. Such studies, however, are utterly unsuited to a routine biochemical department, and still more inappropriately dealt with in a large routine pathological laboratory. Nor do the irksome but essential details of the collection of the urine specimens lend themselves, as one of the speakers in this discussion pointed out, to the hurly-burly of gynæcological outpatients or the antenatal clinic; they would be more appropriately and more efficiently disposed of in a clinic dealing solely with "medical" gynæcology.

Other hormone assays are equally unsuited to the routine laboratory, the busy clinic, or the overworked and understaffed hospital ward. Estimations of 17-ketosteroids are increasingly demanded in the investigation of hirsutism and as an aid to diagnosis in Addison's disease, Simmonds's disease, and myxœdema, though the results are often treated with a respect which they neither deserve nor claim. Too little emphasis is placed by the unenlightened clinician on the wide variation in normal range, and he is too often dazzled by being presented with an absolute gravimetric measurement of this hormonal excretory product. Furthermore, the increasing demand for these estimations is apt to embarrass those biochemists who are known to undertake them. Many clinicians look on œstrogen assays as a logical and reasonable investigation to be undertaken in all sorts of menstrual and other disorders of possible ovarian origin. But in fact they would be significant only if the amount found in the urine was either nil or grossly in excess of normal. Zero figures would indicate ovarian failure but would not localise the primary lesion to the pituitary, on the one hand, or the ovary on the other. The only condition in which high figures would be of diagnostic value is granulosa-cell tumour of the ovary. From the laboratory point of view œstrogen assays are laborious and unsatisfactory. The chemical estimation, based on the Kober colorimetric technique, is still not sufficiently specific, and the biological assay is extravagant in the number of ovariectomised mice required. Furthermore, the figure obtained is only a crude "bracketing" result (more than so many mouse units and less than a larger number of mouse units). Finally, the urinary œstrogen figure represents only one point in the complicated metabolic cycle of œstrogens. The other hormone assay that may be of clinical value is the estimation of pituitary follicle-stimulating hormone (F.S.H.) in the urine. In cases of gonadal deficiency in which the primary lesion is in the gonad, as opposed to the pituitary, F.S.H. values are high. Where the lesion is primarily hypophyseal the F.S.H. value is nil. This would therefore be a most useful aid to the clinician. The biological test for F.S.H.—the production of enlarged follicles in immature rodents—is not very complicated, but a rather laborious preliminary chemical extraction of the urine is necessary, and the test is therefore seldom applied in this country.

The remedy for all these difficulties is obvious. Instead of straining the imagination and obligations of the busy practising gynæcologist or physician in his routine day-to-day work, these problems, at any rate for the time being, should be "seconded" to special endocrine units, of which some already exist. In addition, special endocrine laboratory units, staffed by the best endocrine biochemists and biologists, adequately remunerated both in actual salary and future prospects and assisted by technicians sufficient in number and dexterity to fulfil their declared needs, should be set up. Such clinical laboratory endocrine units would do valuable and progressive research and would, at their leisure, clear the snags from routine hormone assays so that they became part of the smooth collaboration between clinician and laboratory worker.

Cortisone: Results and Possibilities

Rheumatoid arthritis has been regarded by most physicians as an essentially progressive disease: though patients sometimes recover, either under treatment or spontaneously (e.g., in pregnancy or jaundice), recovery has been generally considered exceptional. In his Heberden oration last year Hench[1] argued that this attitude towards the disease should be altered: the physiological changes, at all stages, should be looked on as potentially reversible, and only the anatomical changes in late cases should be accepted as permanent. The soundness of this thesis has been proved by the dramatic work since reported by himself and his associates at the Mayo Clinic. In an attempt to reverse the rheumatic process, they used 17-hydroxy-11-dehydrocorticosterone (Kendall's compound E, now known as 'Cortisone'), and the results exceeded all expectations. Their report[2] on the first 14 cases of rheumatoid arthritis treated shows that in all of them the effect, within a few days, was reduction of stiffness, lessening of pain, and improvement of muscular and articular function: appetite and weight increased, and the patients had a sense of well-being, even to euphoria. On the objective side, the sedimentation-rate fell rapidly, serum proteins were restored to normal, and in anæmic patients there was some rise in hæmoglobin values.

The cortisone was usually given in the form of acetate, and the dose was usually 300 mg. for an initial injection, followed by 100 mg. daily: in some cases 75 mg. was used, but doses of 25 or 50 mg. were ineffective. Unfortunately, a few days after the injections were discontinued, symptoms returned in the majority of patients; and the evidence so far suggests that the treatment may have to continue for life. Side-effects were usually mild, the chief being transient œdema; but in one case, after about three months, there were repeated sudden weight gains of 4–7 lb., and equally sudden weight losses through diuresis (suggesting a disturbance of electrolyte metabolism), acne, mild hirsutism, and rounding of facial contour, with amenorrhœa. In 2 further patients treated with 100 mg. daily of anterior-pituitary adrenocorticotrophic hormone (A.C.T.H.) the improvement was as remarkable as with cortisone, but side-effects were much more troublesome—notably, a sense of exhaustion, transient gas pains, heaviness in the chest, and a rise of blood-pressure. Various other adrenal hormones are under trial, and meanwhile cortisone has been used,[3] with equally striking results, in 3 cases of acute rheumatic fever: its administration for periods of from three to five weeks was associated with rapid disappearance of all clinical symptoms, and return of sedimentation-rate and electrocardiographic patterns to normal, and the hope is expressed that the effect on the cardiac muscle and valves in this disease will be as beneficial as the effect on the fibrous tissue in rheumatoid arthritis. Unlike the patients with rheumatoid arthritis, those with rheumatic fever did not show any early return of symptoms; but the period between cessation of treatment and publication of the preliminary report was very short.

Clearly, we can acclaim a therapeutic discovery of first importance, and it is one that arouses many speculations. Firstly, is cortisone therapy simply replacement therapy? Probably not; for it seems unlikely that normal adrenals produce anything like 100 mg. of the hormone daily. Perhaps the true active agent is something else, and the body is able to convert only a small fraction into the active agent x; or perhaps x is not produced from cortisone at all, and cortisone has an x-like activity at a very much lower level. (Kendall's careful work on purification of the adrenal hormones makes it improbable that cortisone is merely a carrier for traces of the active agent x.) Secondly, the question of side-effects has to be considered. Admittedly, they were serious in only 1 of the treated patients; but only 4 of them had received the hormone for as long as three months, and longer treatment may easily bring greater difficulties. The side-effects of A.C.T.H. were much more conspicuous, as might be expected from a hormone which stimulates the production of more than one adrenal product: such a compound as desoxycorticosterone, in massive doses over a long period, would be expected to produce changes in electrolyte metabolism and a rise in blood-pressure. Thirdly, apart from rheumatic fever and rheumatoid arthritis, there are a number of diseases of unknown ætiology in which it would be interesting to know the action of cortisone. Hench cites the arthritis of lupus erythematosus, of ulcerative colitis, and of psoriasis as possible further examples of temporary deficiencies of adrenal hormone. One would like to know whether such conditions as periarteritis nodosa, serum-sickness, and even some forms of nephritis, will respond; but these questions are not likely to be answered for some time. Though the amazing results obtained by Hench and his colleagues will make everyone want to be in a position to repeat them at the earliest opportunity, we must again quote the statement that "Merck and Co. Inc., . . . regret that because of the exigencies of manufacture, no supplies of Compound E are expected for treatment or additional research until sometime in 1950 at the earliest . . .", a view which the Lord President of the Council confirms in a Parliamentary reply on p. 177.

P.R.C.S.

DIFFERENT people serve the profession in widely different ways. Of Lord Webb-Johnson's contributions to medicine, probably the greatest have been indirect and remain to be realised; for his constant endeavour has been to improve conditions of training and work for the younger generation. He believes in the importance of good environment, alike for education, for research, and for practice, and this belief has found expression both at Middlesex Hospital and at the Royal College of Surgeons, whose presidency he now resigns after eight fruitful years. As a transformer of ancient institutions he has succeeded largely because he can infect others with his enthusiasm; and his hospital and college owe many of their biggest benefactions to his faculty of persuasion. But if a succession of industrial leaders have been happy to provide money for his projects it is because these projects, both great and small, have been at once imaginative and sound. A long series of innovations at the Royal College of Surgeons, including the Nuffield College of Surgical Sciences soon to be constructed, bear witness to a vigour and vision that ensure him a high place among its presidents.

Of Lord Webb-Johnson's contribution to the solution of the medico-political problems of the past few years it would be premature to speak; but here, as in the college itself, his successor, Sir Cecil Wakeley, inherits large responsibilities as well as large opportunities. We wish the new president the success to which in so many fields he is already accustomed.

TRENDS IN CANCER RESEARCH

THE pursuits grouped under the term "cancer research" are so varied and recondite that no one reviewer can appraise all of them. Some trends are easier to discern. One that becomes clear is that in those centres supported by the British Empire Cancer Campaign and based on university departments there is a tendency to deviate into problems of the basic sciences concerned. Thus observations are recorded in the campaign's annual report[1] for 1948, in physical, radiological, chemical, and biochemical sciences which can be judged only by specialists in each field. The relation of the observations to cancer research is not necessarily urgent or even apparent, yet the net thus widely and wisely cast may bring a rich catch of new data of general scientific value by virtue of the subjects tackled and academic standards set. None can tell in what direction the cause and cure of the disease will be found; therefore all evidence as it comes to hand is better tested by the most vigorous methods and as dispassionately as possible, emotional reactions being directed rather at methods of arriving at conclusions than at the conclusions themselves.

In the present report clinical investigations follow traditional lines and include another of the campaign's valuable statistical analyses of cancer, this year of the ovary, vulva, and female urethra, while Sir Ernest Kennaway, F.R.S., and his colleagues continue to throw light on the social incidence of factors affecting tumours of exposed sites, this year of the skin and lip. Cancer of the lip, like that of the scrotum, can be largely eliminated by the conditions of life of the richer classes. Whether this is because new growths of the lip get early attention, for cosmetic reasons, in the more favoured classes is undecided. A general trend in relation to therapy is to obtain more detailed knowledge and control of all promising physical and chemical agents. This is especially evident at the Royal Cancer Hospital.

Contributions to experimental pathology show the fertilising influence of the conception, originated by Peyton Rous, of analysis into initiating and promoting phases of the cancer process. The promoting influence of croton oil, previously studied by I. Berenblum in relation to chemical carcinogenesis of skin tumours, has now been extended by F. R. Selbie to virus tumours, by C. B. Allsopp to water-soluble derivatives of benzpyrene, and by F. Bielchowsky to induced thyroid tumours. Many workers must feel grateful to F. C. Pybus and E. W. Miller for their laborious undertaking to isolate a number of inbred lines of mice, each characterised by a different type of tumour, and in particular to endeavour to repeat Strong's induction of glandular carcinoma of the stomach by methylcholanthrene with the appearance of this tumour as a gene mutant in subsequent untreated generations of offspring. Much time, space, and labour will be required before any conclusion can be reached about this curious observation. These workers have found no type of neoplasm in an injected animal which has not also been seen in an untreated control. There is no evidence that methylcholanthrene intensified the incidence of any tumour except stomach papillomas and lung adenomas.

Finally, a trend to attract, if not create, first-class brains, with £ *s*. *d*. is disclosed by the founding of highly paid senior and junior fellowships in cancer research. This is all to the good. These gifted people will immediately see, what is already apparent to others, that cancer research up to the present has been lacking not only in security of tenure but also in certain basic facilities. Coming into the subject with freshness and independent status, their diagnosis may be heard. Of these deficiencies the gravest are in: (1) housing for large stocks of animals, and (2) staff to care for them; and these take precedence over other difficulties of supply. Although the question of breeding large healthy stocks of strains and species is being solved by establishments in Edinburgh and at Chalfont St. Giles supported by the B.E.C.C., it is always necessary to have an adequate local pool of reserves as well as properly housed and tended experimental stock. It may be noted that members of the Scientific Advisory Committee represent for the most part those institutions where, through foresight of directors and administrators, adequate housing exists. Unless these institutions can absorb all the first-class brains there is likely to be much frustration and disappointment. It is of course undeniable that with clear heads many issues in cancer causation might be cleared up, in the absence of these elemental facilities, by statistical analysis and philosophical discussion of existing data; but new knowledge of the nature of cancer will be gained faster by that special tool of our day—the experimental method and its proper controls.

MUSCULAR CONTRACTION, 1949

THE mechanism of muscular contraction has always baffled and absorbed physiologists. For some time it has held a leading place in their interests, but gradually the force tackling this problem has changed; the shock troops now are protein chemists, electrical engineers, biophysicists, X-ray crystallographers—experts in the energetics of rubber and the detection of infinitesimal amounts of chemical compounds. On July 7 the general staff met at the Royal Society, the principal question discussed being: What chemical event initiates or is associated with the contraction of the muscle-fibre?

Prof. A. V. Hill, F.R.S., speaking of the biophysical findings, explained that the elementary unit of muscular activity is the single muscle twitch. Therein lies the difficulty of analysis, for the twitch is an exceedingly rapid affair; in striated muscle at normal body-temperatures it is over in a few milliseconds. Even using slow unstriated muscles at 0°C, the events are still too fast to be followed by chemical methods; there are in fact no chemical data whatever on what happens during a single twitch. Physical methods, of which the majority have been devised by Hill himself, can follow easily and accurately the heat-production during and after the twitch, the tension development, and electrical and optical changes. Though very hard to interpret, these physical data are clear and reliable. More than anything else they provide a framework into which chemical theories must fit. Some theories can thus be discarded, but more than one can be more or less squared with the physicist's findings.

---

[1] Issued from 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1.

The fundamental event in contraction is the shortening of a particular protein molecule in the myofibril. Prof. H. H. Weber, of Tübingen, observed at the meeting that muscle contains several proteins, of which apparently only two—actin and myosin—are concerned in the actual contractile process. A possible model of the process was given in a communication by Prof. W. T. Astbury F.R.S. Imagine two strips of paper stretching parallel to each other from north to south, and turned edge-on to the observer. Fold each of them like a concertina, so that each is crinkled, running first south-east then south-west, then south-east, and so on. These represent the myosin molecules in the relaxed state. Between these two scatter some tennis-balls—the globular form of actin. When the muscle contracts, said Astbury, the actin tennis-balls arrange themselves in chains, one sticking to another in a straight north-south line; this is now the fibrous form of actin. At the same time the myosin molecule shortens with a concertina action; the crinkles instead of running south-east and south-west run more nearly east and west, and the edges of the crinkles now touch the actin chain. Astbury was led to this picture by X-ray studies, but not all workers in this field agree that it is true. What is needed, he holds, is an X-ray study of muscle actually while it twitches; but here, as in chemical studies, technical difficulties supervene.

What is it, then, that causes the change in form of the actin and myosin molecules and their association? This is the central question, to which there is still no answer. When a nerve impulse reaches the neuromuscular junction a wave of activity spreads down the surface membrane of the fibre, very much as an impulse travels down a nerve. Somehow this surface diminution of electric charge sets off the contractile mechanism in the interior of the fibre; and probably the movement of ions is one of the links in the chain. But is this literally a trigger action? Is the muscle like a stretched spring waiting for a chance to contract—that is, to lower its potential energy? Is contraction or relaxation the more probable state, in the technical sense of the phrase? This is another question on which there is no agreement. Professor Hill holds strongly to the view that contraction is active and relaxation passive, and the relaxed state the lower in potential energy. From physical measurements he cited considerable evidence to support this view; but the evidence is not decisive, and many of the chemists had theoretical reasons for holding the opposite opinion. Since it is believed that the energy source of a twitch is the breakdown of adenosine triphosphate the crucial experiment would be to determine whether this substance breaks down during the contraction phase of the twitch or only when the twitch is over. This is asking too much of the chemists; Mrs. Dorothy Needham, F.R.S., indicated that new spectrophotometric methods might be able to detect chemical changes after a single twitch, but she held out no hope of establishing the time relations of the chemical events.

Bit by bit an intricate cat's-cradle of fact is being woven, but the shape of the cat still eludes us; and one can scarcely see the string for the holes. Not that there is anything mysterious or unique about muscular activity; as Professor Astbury emphasised, the contractile muscular protein molecules are only a special adaptation in a general group which includes keratin, fibrinogen, and the epidermal protein of mammals. In human hair there persists the skeleton of muscle-fibres—the machine without the fire to drive—so the permanent wave has some relation to the athlete's strength.

EFFECTS OF HEAT AND HUMIDITY IN DEEP MINES

AT the first post-war Empire Mining and Metallurgical Congress, the technical sessions of which were held at Oxford from July 12 to 16, interest in man's reactions to underground environments was intensified because of the various factors now increasing the difficulties of the mining industry. Not only is it becoming more difficult in different parts of the world to attract labour into the mines, but it is apparent that in South Africa, India, and even Britain heat and humidity in the deeper mines diminish working efficiency to an unknown extent. By contrast with the outstanding success of personnel research during the war on similar subjects, the mining industries have lagged behind in organising heat physiology units, not only in this country but also in South Africa.

The problems discussed must have left little doubt of the urgent need for further physiological information. A survey of the environmental conditions in British coalmines by Mr. A. E. Crook, Mr. F. Edmond, Mr. J. Ivon Graham, and Mr. B. R. Lawton revealed that in Britain a wet-bulb temperature of 85°F had been reached at 3000 feet below the surface. It was agreed on theoretical grounds by Sir David Brunt, F.R.S., and from Dr. A. Caplan's experience in India, that efficiency for strenuous work falls off at wet-bulb temperatures of 83–85°F. Caplan and J. K. Lindsay assessed the fall in muscular efficiency as 20% at a wet-bulb temperature of 87°F, and at similar temperatures Mackworth has demonstrated a reduction in psychological performance. It might be inferred from the agreement between Caplan and Brunt that Indian mineworkers work at a level of energy output defined as strenuous—i.e., about 300 Kcal./m²/hr. This would be surprising in the light of Dr. J. S. Weiner's observations on the working ability of Bantu mine-labourers in hot humid conditions. Weiner demonstrated that "raw" and "experienced" Bantu are less well adapted to hot humid environments than young healthy Europeans, acclimatised in experimental chambers. It is suggested that Bantu labourers normally work at a lower energy output than that of the acclimatisation routine (110 Kcal./m²/hr.). There is no information on the energy output at the various tasks in mining. This extraordinary gap in our knowledge delays the use by ventilation engineers and physiologists of Brunt's integration into a vastly improved thermal balance equation of the factors concerned in heat-production and its transmission to and dissipation from the body surface to the environment. Thermal balance may be expressed simply as:

$$\begin{array}{c}\text{Heat-production}\\ +\ \text{heat-storage}\end{array} = \begin{array}{c}\text{heat-loss by evaporation}\\ +\ \text{convection} + \text{radiation.}\end{array}$$

But energy exchanges by convection and radiation cannot be measured directly. C. E. A. Winslow, in 1941, determined these factors experimentally, in terms of mean temperature of the skin and the walls and the dry-bulb thermometer reading. Brunt has integrated Winslow's with his earlier work and expressed convection, evaporation, and radiation in terms of readily measurable quantities, thus:

$$\begin{array}{c}\text{Heat-production}\\ +\ \text{heat-storage}\end{array} = 3{\cdot}6\,(T_s - T_r) + 66{\cdot}7\sqrt{v}\,(I_s - I_w)$$

where T_s is mean skin temperature; T_r is mean temperature of walls; I_s and I_w are the total heat content of unit mass of dry air, *plus* the water required to saturate it, at skin temperature of the wet-bulb thermometer of the ambient air.

Even using slow unstriated muscles at 0°C, the events are still too fast to be followed by chemical methods; there are in fact no chemical data whatever on what happens during a single twitch. Physical methods, of which the majority have been devised by Hill himself, can follow easily and accurately the heat-production during and after the twitch, the tension development, and electrical and optical changes. Though very hard to interpret, these physical data are clear and reliable. More than anything else they provide a framework into which chemical theories must fit. Some theories can thus be discarded, but more than one can be more or less squared with the physicist's findings.

---

[1] Issued from 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1.

The fundamental event in contraction is the shortening of a particular protein molecule in the myofibril. Prof. H. H. Weber, of Tübingen, observed at the meeting that muscle contains several proteins, of which apparently only two—actin and myosin—are concerned in the actual contractile process. A possible model of the process was given in a communication by Prof. W. T. Astbury F.R.S. Imagine two strips of paper stretching parallel to each other from north to south, and turned edge-on to the observer. Fold each of them like a concertina, so that each is crinkled, running first south-east then south-west, then south-east, and so on. These represent the myosin molecules in the relaxed state. Between these two scatter some tennis-balls—the globular form of actin. When the muscle contracts, said Astbury, the actin tennis-balls arrange themselves in chains, one sticking to another in a straight north-south line; this is now the fibrous form of actin. At the same time the myosin molecule shortens with a concertina action; the crinkles instead of running south-east and south-west run more nearly east and west, and the edges of the crinkles now touch the actin chain. Astbury was led to this picture by X-ray studies, but not all workers in this field agree that it is true. What is needed, he holds, is an X-ray study of muscle actually while it twitches; but here, as in chemical studies, technical difficulties supervene.

What is it, then, that causes the change in form of the actin and myosin molecules and their association? This is the central question, to which there is still no answer. When a nerve impulse reaches the neuromuscular junction a wave of activity spreads down the surface membrane of the fibre, very much as an impulse travels down a nerve. Somehow this surface diminution of electric charge sets off the contractile mechanism in the interior of the fibre; and probably the movement of ions is one of the links in the chain. But is this literally a trigger action? Is the muscle like a stretched spring waiting for a chance to contract—that is, to lower its potential energy? Is contraction or relaxation the more probable state, *in the technical sense of the phrase*? This is another question on which there is no agreement. Professor Hill holds strongly to the view that contraction is active and relaxation passive, and the relaxed state the lower in potential energy. From physical measurements he cited considerable evidence to support this view; but the evidence is not decisive, and many of the chemists had theoretical reasons for holding the opposite opinion. Since it is believed that the energy source of a twitch is the breakdown of adenosine triphosphate the crucial experiment would be to determine whether this substance breaks down during the contraction phase of the twitch or only when the twitch is over. This is asking too much of the chemists; Mrs. Dorothy Needham, F.R.S., indicated that new spectrophotometric methods might be able to detect chemical changes after a single twitch, but she held out no hope of establishing the time-relations of the chemical events.

Bit by bit an intricate cat's-cradle of fact is being woven, but the shape of the cat still eludes us; and one can scarcely see the string for the holes. Not that there is anything mysterious or unique about muscular activity; as Professor Astbury emphasised, the contractile muscular protein molecules are only a special adaptation in a general group which includes keratin, fibrinogen, and the epidermal protein of mammals. In human hair there persists the skeleton of muscle-fibres—the machine without the fire to drive—so the permanent wave has some relation to the athlete's strength.

EFFECTS OF HEAT AND HUMIDITY IN DEEP MINES

AT the first post-war Empire Mining and Metallurgical Congress, the technical sessions of which were held at Oxford from July 12 to 16, interest in man's reactions to underground environments was intensified because of the various factors now increasing the difficulties of the mining industry. Not only is it becoming more difficult in different parts of the world to attract labour into the mines, but it is apparent that in South Africa, India, and even Britain heat and humidity in the deeper mines diminish working efficiency to an unknown extent. By contrast with the outstanding success of personnel research during the war on similar subjects, the mining industries have lagged behind in organising heat physiology units, not only in this country but also in South Africa.

The problems discussed must have left little doubt of the urgent need for further physiological information. A survey of the environmental conditions in British coalmines by Mr. A. E. Crook, Mr. F. Edmond, Mr. J. Ivon Graham, and Mr. B. R. Lawton revealed that in Britain a wet-bulb temperature of 85°F had been reached at 3000 feet below the surface. It was agreed on theoretical grounds by Sir David Brunt, F.R.S., and from Dr. A. Caplan's experience in India, that efficiency for strenuous work falls off at wet-bulb temperatures of 83–85°F. Caplan and J. K. Lindsay assessed the fall in muscular efficiency as 20% at a wet-bulb temperature of 87°F, and at similar temperatures Mackworth has demonstrated a reduction in psychological performance. It might be inferred from the agreement between Caplan and Brunt that Indian mineworkers work at a level of energy output defined as strenuous—i.e., about 300 Kcal./m²/hr. This would be surprising in the light of Dr. J. S. Weiner's observations on the working ability of Bantu mine-labourers in hot humid conditions. Weiner demonstrated that "raw" and "experienced" Bantu are less well adapted to hot humid environments than young healthy Europeans, acclimatised in experimental chambers. It is suggested that Bantu labourers normally work at a lower energy output than that of the acclimatisation routine (110 Kcal./m²/hr.). There is no information on the energy output at the various tasks in mining. This extraordinary gap in our knowledge delays the use by ventilation engineers and physiologists of Brunt's integration into a vastly improved thermal balance equation of the factors concerned in heat-production and its transmission to and dissipation from the body surface to the environment. Thermal balance may be expressed simply as:

$$\begin{array}{c}\text{Heat-production}\\ +\ \text{heat-storage}\end{array} = \begin{array}{c}\text{heat-loss by evaporation}\\ +\ \text{convection} + \text{radiation.}\end{array}$$

But energy exchanges by convection and radiation cannot be measured directly. C. E. A. Winslow, in 1941, determined these factors experimentally, in terms of mean temperature of the skin and the walls and the dry-bulb thermometer reading. Brunt has *integrated* Winslow's with his earlier work and expressed convection, evaporation, and radiation in terms of readily measurable quantities, thus:

$$\begin{array}{c}\text{Heat-production}\\ +\ \text{heat-storage}\end{array} = 3{\cdot}6\,(T_s - T_r) + 66{\cdot}7\sqrt{v}\,(I_s - I_w)$$

where T_s is mean skin temperature; T_r is mean temperature of walls; I_s and I_w are the total heat content of unit mass of dry air, *plus* the water required to saturate it, at skin temperature of the wet-bulb thermometer of the *ambient air*.

On the basis of the body temperature reaching a steady state—i.e., when heat-storage = 0—Brunt produced a nomogram for the limiting environmental conditions in terms of wet-bulb temperature and temperature of the walls for three different rates of energy production. Experimental verification of these limiting conditions is found in S. Robinson's work in the United States. There is an obvious advantage, either from a physiological or an engineering point of view, in being able to measure in heat units the heat-load of the environment on the human body. Previous scales of warmth have assessed equivalent effects and relative severity of various combinations of heat, humidity, and air movement in terms of single physiological effects such as the subjective sensation of warmth (effective temperature scale) or of the sweat-output in 4 hours at a standard work-rate (predicted 4-hourly sweat-rate). Dr. A. O. Dreosti's pioneer work in 1932 on acclimatisation and on the "heat-tolerance test," has been amply verified in the reduction in deaths from heat-stroke. Investigation of recent heat deaths in South African mines shows that each was due to some departure from Dreosti's rules.

HOSPITAL ADMINISTRATION IN NEW ZEALAND

THE hospitals of New Zealand are governed by forty-two boards elected directly by the people in much the same way that local councils are elected in Britain. These boards were first set up in 1910, since when the development of road and air transport and the changes in population distribution and the size of homes and families, to say nothing of medical progress, have quite outmoded the original conception of separate bodies serving fairly small isolated populations.

The need for early reorganisation is argued by Mr. Selwyn Morris and Mr. Douglas Robb[1]—two surgeons who have already contributed much to our understanding of the health service in their country. In their words,

> "the things that are wrong now are mainly due to faulty organisation. They include the too large number of too small and unrelated administrative units. The constitution of the Hospital Boards in being wholly selected by popular vote, the unchecked overlap between general medical service and hospital work (both paid for by the Social Security Fund), the little use of the recovery or convalescent hospital and the polyclinic for specialist investigation, the little attention given to the care of the aged, and the division of authority between the local Hospital Board, on the one hand, and the Government Departmental Office, and the Ministerial Office in Wellington."

The solution they propose is the division of the country into six hospital regions each caring for some 300,000 people. These regions they believe would be large enough for autonomous development on a functional basis; each would provide all services except the super-specialties like brain or heart surgery. "In this way all the more specialised services are brought to the region, and so nearer home, and the regional board is obliged to provide itself with a full range of buildings, equipment, and professional skill. To make the regional unit smaller would make it incomplete and so partially dependent on remoter control and help." All the proposed administrative bodies, from the new local hospital boards through the regional boards to a central national hospitals' corporation, are designed to give representation not only to the people (indirectly through their local councils) but also to the doctors and nurses working in the service. The principal medical and nursing officers should, it is suggested, be included as full members of the board or corporation which they serve; while at regional and national levels there should be university representation. The national hospitals' corporation would include a representative of each region together with university and ministerial nominees, and it would deal with questions of national policy over such matters as clinical records, vital statistics, and diseases such as tuberculosis requiring some measure of national planning. It would also watch over the distribution of finance both for current expenditure and for capital works. A small peripatetic commission appointed by this corporation should advise (after the fashion of the University Grants Committee) on the allocation of funds.

The British reader of this pamphlet will find much to stimulate his interest, many problems common to our two countries, and many analogies in the solutions suggested to the methods we have been trying to initiate during this last year. Some problems only beginning to appear here—such as the extent to which a hospital outpatient department can properly be required to undertake duties within the scope and the terms of service of the general practitioner—have obviously been apparent in New Zealand much longer, though even there no solution seems to be in sight. Perhaps this particular problem will not be solved in either country without the development of health centres, and a division of function between these and the hospitals.

CONSULTANTS' AND SPECIALISTS' CONTRACTS

As reported in our issue of July 9, the Joint Committee, formed by the Royal Colleges and the British Medical Association, decided on July 5 to reopen discussions with the Ministry on three points—conciliation machinery and arbitration, facilities for private treatment in hospitals, and the remuneration of part-time clinical teachers. After receiving the Ministry's letter which we printed last week, the Joint Committee met representatives of the Ministry on July 18, when the following assurances were received:

Arbitration.—The Ministry has agreed:

(*a*) That no changes will be made in the terms and conditions of service without discussion in the appropriate part of the Whitley machinery, when established, and this will be established as soon as possible.

(*b*) That remuneration is a subject which is suitable for arbitration.

(*c*) That save in exceptional circumstances, and after the conciliation machinery of Whitley has been exhausted, issues of remuneration remaining in dispute will go either to arbitration or for inquiry and report by a committee.

(*d*) That the words "by the Minister of Health" will be deleted from the opening paragraph of the model contract, so that it would simply refer to the terms and conditions of service "determined from time to time."

Private Practice.—The Ministry reiterated its previous assurances that it was not its intention to place difficulties in the way of private practice. It has agreed that patients admitted to private hospital beds under section 5 of the Act will pay fees for professional attendance to part-time practitioners in addition to the maintenance charges; except where the patient is occupying accommodation under the proviso to section 5 (1)—i.e., on medical grounds.

The Ministry has also agreed that individual practitioners are free to leave untouched or to delete from the whole-time contract any of the clauses which are enclosed in square brackets, including clause 5 requiring attendance on patients occupying beds under section 5 of the Act who have not made *private arrangements under section 5 (2).*

Clinical Teachers.—Assurances, shortly to be made public, have been received on the arrangements for the remuneration of clinical teachers.

The Joint Committee decided, with the assent of the Ministry, to continue negotiations on a number of outstanding points. It feels that it is now able to advise hospital staffs to enter into permanent contracts.

SIR DOUGLAS COOKE, F.R.C.S., Conservative M.P. for South Hammersmith from 1931 to 1945, died in London on July 13 at the age of 70.

CONGRESS OF OBSTETRICS AND GYNÆCOLOGY

THE twelfth British congress of obstetrics and gynæcology was held on July 6, 7, and 8, under the presidency Sir EARDLEY HOLLAND.

MODERN CÆSAREAN SECTION

At the first meeting Mr. C. MCINTOSH MARSHALL called that in 1921 Munro Kerr and Eardley Holland rveyed the operation of cæsarean section up to that me. Their survey had covered 4568 cæsarean sections ith a maternal mortality of 6·9%. A further survey, st completed, of 7762 cæsarean sections performed for l *indications in 16 maternity hospitals between 1943* d 1947 had recorded a maternal mortality of 0·99%. he total incidence of cæsarean section in the latest rvey was 6·2%. The incidence had increased owing several factors: toxæmia was now a major indication r the operation, which was also more widely used in lacenta prævia; moreover, there was a relative increase the use of elective cæsarean section among the large umber of abnormal confinements in the teaching ospitals, where these figures were collected. He ttributed the improvement in the results to wider mployment of *the lower-segment operation, to the use* f sulphonamides *and more recently* penicillin, and to lood-transfusion. Of the classical cæsarean section he as willing to speak only with great reserve, and in ublic never at all. He believed that with severe lminating toxæmia it was necessary to perform cæsarean ection in order to secure a living baby, and since 1934 e had regarded all cases of true pre-eclampsia as no less rgent than those of "acute abdomen." Half the fœtal ortality was in infants of women operated on for erious diseases such as placenta prævia, toxæmia, and iabetes. Even among the elective cases fœtal mortality as fairly high; no woman could be assured of a living hild by abdominal delivery, while for those operated on ate *in labour* the fœtal mortality was still greater. he lower-segment operation was always indicated with lacenta prævia, except its minor variations; he nearly lways diagnosed this complication by the history and bdominal findings and he did not think it necessary to ake a vaginal examination with its attendant risks. s to anæsthesia he did not insist as formerly on local nfiltration, for he believed that curare and cyclopropane ere improvements. At the Liverpool Maternity Hospital ost patients with severe cardiac disease were delivered y cæsarean section; between 1939 and 1948 there were 97 vaginal deliveries with a maternal mortality of 3·36%, nd 98 cæsarean sections with a maternal mortality f 2·04%.

Dr. NINIAN FALKINER thought that the incidence of æsarean section reported by Mr. Marshall was very igh; he could not agree to the performance of this peration for late toxæmia. The lower-segment operaion was undoubtedly preferable. In his figures the aternal mortality was: lower-segment 0·44%, classical ·28%.

Mr. A. W. PURDIE had investigated the incidence of æsarean section in the Middlesex county hospitals in 1943–47. His figures, from busy non-teaching hospitals, might be compared with Mr. Marshall's from the teaching hospitals. In the Middlesex county hospitals emergencies were never refused; there were altogether 1667 perations with 23 deaths, giving a maternal mortality f 1·38%. The incidence of cæsarean section in this roup was 3·23%, and 80% of these operations were of he lower-segment type.

Mr. FRANK STABLER said that some years ago Munro Kerr had observed that in view of a reported 12·3% maternal mortality from cæsarean section after the application of forceps, few would use this operation in preference to embryotomy. But Mr. Stabler had lately found from reports of the Glasgow Maternity Hospital for the same time that the maternal mortality after embryotomy was 20·7%; and in Newcastle during the last ten years there had been 33 cæsarean sections after forceps with one death. He believed that penicillin and sulphonamides would reduce the death-rate from embryotomy, but he doubted whether the rate could be reduced as low as that achieved with the lower-segment cæsarean section.

Dr. J. KEVIN FEENEY believed that far too many cæsarean sections were being performed. For disproportion, induction of labour was a very satisfactory method; and there should be fewer cæsarean sections for placenta prævia.

Prof. J. M. MUNRO KERR, who spoke at the president's invitation, said it was ridiculous for a man of his age to take part in a discussion on modern cæsarean section; the two series quoted by Mr. Marshall illustrated the evolution of cæsarean section, and he would like the congress to join with him in the hymn, "The strife is o'er, the battle won."

Prof. DUGALD BAIRD differed slightly from Mr. Marshall, and asked "Where do we go from here?" He was a little doubtful whether so many cæsarean sections were necessary, particularly where uterine inertia was an indication.

Prof. A. SUNDE (Oslo) said that in his hospital the incidence of cæsarean section had increased from 3% to 11%; the maternal mortality was 0·3%. In 60% disproportion was the indication, and in 18% placenta prævia. Contracted pelvis was rare in Norway, but nearly all the cases went to hospital for delivery. Cæsarean section was not performed for toxæmia or eclampsia; nor was elderly primaparity by itself regarded as an indication for the operation.

Prof. W. C. W. NIXON suggested that while it was all very well to say that too many cæsarean sections were being done, it was very important that a woman should not lose her first baby; and until there was a safe drug with which to counter uterine inertia it was right and proper to employ cæsarean section for this complication.

Mr. MARSHALL, in reply, pointed out that he personally did not perform all the 7000 cæsarean sections; and from Chicago there was a report of 1000 cæsarean sections, for all indications, with one death. He believed that an increase in the scope of the indications was justified by the greatly decreased mortality of the operation.

ENDOMETRIOSIS

At this session, with Prof. HILDA LLOYD in the chair, a guest paper was presented by Dr. JOE V. MEIGS (Massachusetts). He pointed out that endometriosis was no new disease; it was first described by von Recklinghausen in 1893. The lesions had since been recognised in many bizarre situations—the arm, the leg, and the pleura—and probably occurred unrecognised elsewhere. With regard to ætiology, Dr. Meigs reviewed Sampson's theory of reflux of endometrial debris through the fimbriated ends of the tubes; in passing, he emphasised that Sampson had never advocated castration as a treatment, but had merely observed that atrophy of the lesions followed this procedure. He himself favoured Meyer's theory that the lesions arose from the cœlomic epithelium; but it was possible that pieces of viable endometrium might be carried in the blood-stream, especially via the recently described vena caval bypass in the region of the vertebral column. Pain, acquired dysmenorrhœa, and infertility were the commonest presenting symptoms, and the stilbœstrol test might aid diagnosis. Treatment, he insisted, was essentially conservative. There was no place for castration; since castration caused unwelcome effects outside the cessation of sexual function, the ovaries should be left, even in a patient of 50. In lesions of the alimentary canal he favoured resection of gut rather than castration. As conservative surgery was so satisfactory, sex hormones were not needed in treatment. Dr. Meigs went on to consider the significance of endometriosis. What effect, he asked, had it on women? Was it the cause or the effect of infertility? It arose, he suggested, as the result of delay between the menarche and the first pregnancy; this delay was commonest in those social groups that were mainly affected by the disease.

PREGNANEDIOL IN THE URINE

This discussion was introduced by Prof. G. F. **Marrian**, F.R.S., who dealt with the biochemical aspect. *He concluded that the urinary excretion of pregnanediol* might not be quantitatively related to endogenous secretion of progesterone, and that theoretically estimations of urinary pregnanediol were of little clinical use.

Dr. G. I. M. **Swyer** reported the results of investigations into the clinical usefulness of pregnanediol assay: (1) as a diagnostic test for pregnancy; (2) as a prognostic test in threatened abortion; (3) as a test of the likelihood of labour being initiated by induction; and (4) as a diagnostic aid in complications of pregnancy. He concluded that in (1) and (3) it was unreliable; in (2) it might be useful as an indication for treatment with progesterone; while in (4) it might be of some value in cases of hydatidiform mole, where pregnanediol appeared to be absent from the urine. He did not think that urinary-pregnanediol assay had much to offer the clinician.

In the discussion Mr. S. **Bender** pointed out that indiscriminate progesterone therapy did not affect the outcome of threatened abortion; but administration of progesterone when the urinary pregnanediol was low significantly increased the salvage-rate.

Dr. P. M. F. **Bishop** believed that at present pregnanediol assays were too elaborate and time-consuming, calling for close coöperation between clinic and laboratory, and were of small clinical value. He suggested the establishment of special endocrine laboratories.

ESSENTIAL HYPERTENSION IN PREGNANCY

Mr. S. B. **Herd** was the chairman at this session; and the discussion was introduced by Prof. G. W. **Pickering**, who dealt mainly with the ætiology of hypertension. He underlined the paramount importance of familial predisposition, pointing out that this is inherited as a mendelian dominant. The onset was gradual, so there was little chance of investigating the manner in which the disease was contracted. He distinguished "benign" from "malignant" hypertension; with benign hypertension the diastolic pressure was usually less than 130 mm. Hg, whereas with malignant hypertension it exceeded this figure. Though arbitrary, this was a useful dividing-line. In the benign cases changes in the ocular fundus were mainly arteriosclerotic, whereas in the malignant cases the changes were those of albuminuric retinitis and there was also papillœdema and a raised cerebrospinal-fluid pressure. The benign cases ran a chronic course for many years, with death usually from cardiac failure, apoplexy, or intercurrent disease; whereas the malignant cases ran a short course with death from uræmia. The difference between the two was mainly one of degree. Hypertension was due to vasoconstriction, which was independent of nervous control. Discussing the part played by renin, he pointed out that in chronic hypertension the amount of this substance in renal blood was not increased; and the hypertension was likely to persist even when the original source of renin was removed by extirpating the ischæmic kidney. In a comparative study of hypertensive and non-hypertensive cases, cardiac output and the rate of blood-flow through most organs investigated did not differ greatly; but in hypertension the blood-flow was known to be diminished in the kidney and increased in muscle. He wished that this kind of investigation had been more widely extended to cases during pregnancy. About a third of hypertensive women showed an increase in their high blood-pressure and the onset of albuminuria during pregnancy and in a few of these malignant hypertension would appear. The stimulus for hypertension starting in pregnancy was probably chemical and the origin uterine or possibly the adrenal and pituitary glands. The trouble might originate in uterine ischæmia, though experimental results were so far inconclusive. The pressor substances did not appear to cross the placenta, and the fœtal blood-pressure remained normal. The cause of toxæmia was as great a mystery as ever.

Prof. F. J. **Browne** dealt mainly with the clinical aspects of hypertension in pregnancy. He estimated that it constituted 25% of all the toxæmias of pregnancy; the remaining 75% were made up of cases of pre-eclamptic toxæmia (70%) and chronic glomerular nephritis (5%). In diagnosing essential hypertension, previous history and the finding of a raised blood-pressure before the twentieth week were of paramount importance; pre-eclamptic toxæmia hardly ever started before the twentieth week. Of such cases 40% reached term successfully and produced a living child; 60%, however, suffered an exacerbation, and a fifth of these underwent a rise in blood-pressure sufficient to produce albuminuria. This point was usually reached at a systolic pressure of 160 mm. Hg, and thereafter the fœtus continued in hourly peril of intra-uterine death. The mechanism was spasm of the afferent arterioles supplying the glomeruli, which produced capillary anoxia and therefore leakage of albumin. The mechanism in the maternal constituents of the placenta was similar, anoxia leading to capillary rupture and retroplacental bleeding. The aim should be to keep the blood-pressure below this critical figure. Nevertheless many patients with a systolic blood-pressure of more than 180 mm. Hg went through their pregnancy successfully; in these cases some compensatory mechanism seemed to be at work. In women starting pregnancy with a blood-pressure of over 150/100 mm. Hg the chances of a living child were only one in three. As to reducing the blood-pressure below the critical figure, confinement to bed in hospital was still the principal method of treatment. Venesection, veratrum viride, and tetraethylammonium bromide were either insufficiently reliable or insufficiently safe to occupy a very important place. The obstetrical treatment resolved itself into the choice of method for terminating pregnancy and of the moment for doing so. He disliked rupture of the forewaters because of the softness of the baby's head. Episiotomy, if used, should be wide. At all costs morphine should be withheld; vitamin K might be useful in discouraging hæmorrhage in the newborn. He thought that classical cæsarean section still had a place in the delivery of toxæmic premature babies. Where the kidneys were sound and there was no advanced arteriosclerosis, sympathectomy afforded good hopes of improving the outlook in pregnancy. The prognosis for the child depended largely on the size of the placenta, and not wholly on the actual height of the blood-pressure. There was no significant difference in he incidence of hypertension between parous and non-parous women in the country as a whole, but 50% of patients who developed pre-eclampsia were likely to develop chronic hypertension. Of hypertensive women who became pregnant, 60% developed a superadded pre-eclampsia, and the condition of 30% would be permanently aggravated. Finally, hypertension was not aggravated by pregnancy unless pre-eclampsia was superadded.

Mr. G. F. **Gibberd** denounced " mutilating " operations on the nervous system in our present ignorance.

Mr. A. **Dickson Wright** described his experiences of sympathectomy in 45 cases of hypertension associated with pregnancy. All were severely incapacitated by hypertensive symptoms. In many the improvement after operation was dramatic, and on the whole the prognosis was better where hypertension was a direct sequel to pregnancy. Of his cases 3 had subsequently become pregnant and had gone successfully through their pregnancies, though one was now going downhill. He had not yet performed this operation during pregnancy.

Prof. R. J. **Kellar** regretted the lack of knowledge about the rate of blood-flow, especially to the uterus. The cardiac output was highest in mid-pregnancy—a period which coincided with the lowest phase of the blood-pressure. He had found a rise in cardiac output in 8 pre-eclamptic patients.

Mr. G. J. **Sophian** supported the view that renal sympathetic stimulation was the primary factor leading to the permanent residual lesions in the blood-vessels which perpetuated the hypertension.

Prof. T. N. A. **Jeffcoate** said that the risks to the child were due to interference with placental circulation, and these risks had to be nicely balanced against the risks inherent in prematurity from termination of pregnancy; in such cases cæsarean section might be indicated purely in the interests of the child. Of 1200 cases, 120 were delivered by cæsarean section; the worst cases were those so delivered, yet the fœtal survival figure actually equalled that in the mildest cases delivered normally at term.

PREGNANCY IN DIABETICS

At this meeting the chair was taken by Dr. **John Hewitt.** The discussion was introduced by Mr. **John Peel** and Dr. **W. G. Oakley.** Mr. Peel dealt with the obstetric aspect, while Dr. Oakley reviewed the problem from the viewpoint of the physician.

It was pointed out that, with the successful treatment of the juvenile and adolescent diabetic, a larger number of young diabetic women than hitherto were reaching child-bearing age. Nevertheless, diabetes and pregnancy together were still comparatively rare. At King's College Hospital there was a large diabetic department, and it had been possible to collect data on 141 instances between January, 1942, and March, 1949; a further 458 cases were collected by means of a questionary. The results were analysed in relation to the prediabetic and diabetic states. In the former the fœtal mortality greatly exceeded that for normal pregnancies. The incidence of large babies (10 lb. and over) was found to be high in prediabetic pregnancies, with a maximum in the period furthest from the onset of diabetes. Provided there was proper control, the maternal mortality was only slightly influenced by the diabetic state. Morbidity was difficult to evaluate, but during the puerperium a significant number of patients had poor lactation; perhaps this again implicated the pituitary gland, dysfunction of which, it had been suggested, might account for the original diabetes and the overweight babies.

Even in well-controlled diabetics the fœtal mortality was still appallingly high, and it did not appear to vary if there were short periods of ketosis or hypoglycæmia during the pregnancy. A high fœtal loss was associated with hydramnios, which was a common complication. The babies from cases of hydramnios were significantly larger than those from cases without it; since the size of the placenta was directly related to the size of the baby, it would seem that some factor was acting through the placenta and causing not only the hydramnios, excessively large baby, and high fœtal loss, but also usually the toxæmia of pregnancy. Toxæmia was far more common in diabetic pregnancies. Fœtal loss from this cause was great if the pregnancy was allowed to continue beyond 37 weeks. Possibly a common factor caused toxæmia and intra-uterine fœtal death. The incidence of intra-uterine death rose gradually in the last 6 weeks of pregnancy, but the neonatal death-rate fell slowly towards term. Nevertheless, fœtal loss from cæsarean section did not differ greatly whether the operation was done before or after the 37th week. Results showed that cæsarean section at 36 weeks was associated with only half the fœtal mortality from spontaneous or induced labour. Many neonatal deaths took place in the first 48 hours after delivery; and here once again a diabetic factor was evidently operating. There was, however, no good evidence that hypoglycæmia was a cause of death.

Dr. G. **Douglas Matthew** observed that in his experience stilbœstrol therapy had not affected the onset of pre-eclampsia. Intra-uterine death might be caused by a period in which the diabetes was uncontrolled.

Dr. **Petersen** (Copenhagen) pointed out that the younger the age of onset of diabetes in the mother, the higher was the fœtal mortality. Good results were obtained if the baby was starved for the first 48 hours.

Mr. H. H. **Fouracre Barns** suggested that early termination of pregnancy did not affect the eventual outcome for the baby, but merely transferred deaths from one column to another. Stilbœstrol, acting as a depressant of the anterior pituitary, did increase the salvage of infants when the pregnancy was allowed to go to term.

Prof. F. J. **Browne** did not believe that hypoglycæmia was the cause of neonatal death, and directed attention to the hypertrophy of the heart and adrenal cortex in these babies.

HERNIA OF THE POUCH OF DOUGLAS

Mr. C. D. **Read** said that enterocele had been recognised for generations, but its importance had on the whole been sadly neglected. For the last hundred years anatomists had realised the importance of the rectogenital space. At birth the pouch often extended to the perineal body and was obliterated later by fusion of the peritoneal walls of the sac. In adults the depth of the pouch varied greatly; the analogy of the preformed sac in hernias generally was obvious, and this might sometimes be a factor. Pulsion enteroceles might result from increased intra-abdominal tension associated with adiposity or large tumours; they were also found in slim, asthenic patients. Ventrifixation of the uterus might concentrate the downward thrust along the inclined plane formed by the posterior wall of the uterus, and so predispose to enterocele formation. Traction enteroceles were formed as a result of uterovaginal prolapse; and rectal prolapse was often associated with enterocele formation. The cure of enteroceles depended on excision and closure of the orifice of the sac, and adequate support from below by a sling constructed from the uterosacral ligaments. Simple inversion of the sac resulted in a peritoneal cyst. Enteroceles associated with uterovaginal prolapse were operated on by the vaginal route, either by the Manchester type of operation or by vaginal hysterectomy with repair. In patients on whom an otherwise successful operation for uterovaginal prolapse had previously been done, the operation could be performed by the abdominal or by a combined abdominovaginal approach. Mr. Read urged adequate repair of enterocele, and a search for its presence in all cases of uterovaginal prolapse.

Mr. A. A. Gemmell said that in his experience enterocele was rare; the condition usually arose after operation for uterovaginal prolapse, and was due to subsequent vaginal delivery, the menopause, or an inadequate primary operation. It could be prevented by adequate posterior repair at the first operation. He thought that the uterosacral ligaments might be difficult to identify from below.

Mr. A. C. Palmer considered enterocele to be a standard finding in cases of procidentia. It was repaired by reconstitution of the pelvic floor, removal of the uterus being an essential preliminary.

Mr. C. M. Gwillim drew attention to the high rectocele, which was not sufficiently recognised. An enterocele could be recognised only by inserting a finger into the pouch; and it was best repaired after vaginal hysterectomy.

Mr. Victor Bonney objected to the term "hernia of the pouch of Douglas." Twenty-five years ago he had pointed out that the pouch was a natural hernial sac. Pulsion was of use in defæcation; and obliteration of the sac—e.g., after Wertheim's operation—was followed by annoying constipation. He preferred the term "prolapse of the posterior vaginal vault." The uterosacral ligaments were *not* a separate entity but the posterior edge of the fan-shaped cardinal ligament.

Dr. Joe Meigs (Massachusetts) said there was no hernia of the pouch of Douglas unless it prolapsed through the anus.

Mr. V. B. Green-Armytage favoured the old operation of vaginopexy.

Mr. F. E. Stabler pointed out that the inferior surface of the peritoneum could be recognised by the presence of extraperitoneal fat.

Mr. Read, in reply, said that constipation after Wertheim's operation was probably due to destruction of nervous pathways rather than to obliteration of the pouch of Douglas. He likened the operation of vaginopexy for enterocele to ventrifixation for uterovaginal prolapse.

CARCINOMA OF THE UTERUS

This meeting, under the chairmanship of Prof. O'Donel T. D. Browne, opened with an account by Dr. J. Ernest Ayre (Montreal) of the diagnosis of uterine cancer by cytology. As long ago as A.D. 131 Galen had said that if cancer was to be cured diagnosis must be early, but in almost 2000 years since then no method of securing early diagnosis had been perfected. For the last 75 years pathologists had tried to foretell the behaviour of cancer by biopsy, but unfortunately the test was seldom made early enough for the end-result to be controlled. In 1928 Papanicolaou reported cancer cells in the vaginal secretions of women with carcinoma of the cervix. This had been confirmed in Dr. Ayre's own laboratory, where it was found that the test was even more reliable when the secretions were aspirated directly from the external os rather than from the pouch of Douglas; a scraping of the squamocolumnar junction proved very reliable in the search for malignant cells in clinically undiagnosable carcinoma of the cervix. Between June, 1945, and February, 1949, 3605 cases of uterine carcinoma had been studied in his laboratory; among these there had been 15 false negative and 16 false positive results.

Prof. G. I. Strachan, who spoke on precancerous changes in the cervix, drew attention to the value of the Hinselmann colposcope in detecting leucoplakia of the cervix.

Dr. Alfred Glucksmann described the method developed by him, in conjunction with Dr. F. G. Spear, for detecting radioresistant tumours; and he showed that the results obtained from the radiotherapeutic treatment of carcinomas of the cervix were better in the differentiating type of tumour than in the anaplastic type in the same stage. To assess the radiosensitivity of tumours, the cell-count method had been introduced. For this it was necessary, during a course of radiotherapy, to obtain repeated biopsies of the growing edge of the tumour, which contained young foci. In 97% of 187 cases that had now passed the five-year mark the histo- [illegible] greed with the final clinical result. It [illegible] that this method could be relied on to show whether or not the tumour could be cured by radiotherapy; and if the tumour was not responding favourably to radiotherapy, this would be an indication for surgery. Encouraging preliminary results had been obtained in a study on these lines which he was carrying out with Mr. Stanley Way.

Dr. Alexander Brunschwig (New York) described two types of operation for uncontrolled uterine cancer: (1) complete excision of the vagina, uterus, bladder, and pelvic lymph-nodes with bilateral implantation of the ureters into the pelvic colon; and (2) complete exenteration—that is, excision of the bladder, vagina, pelvic colon, and the entire perineum, and implantation of both ureters into the pelvic colon above an end-colostomy.

Dr. Joe V. Meigs (Boston, Mass.) said that because some patients with early carcinoma of the cervix did not respond well to irradiation he had begun to employ surgery, and in 1944 he presented five reasons for preferring surgery to irradiation:

(1) If the cervix was removed there was no chance of the tumour recurring in it;

(2) if the cervix was removed no cervical cancer could regrow in it;

(3) certain cancers of the cervix were radioresistant;

(4) there would be less damage to the bowel if surgery was undertaken; and

(5) from the work of Bonney and Taussig it was obvious that patients with lymph-node metastases could sometimes be cured by surgery, but it did not seem possible to cure these cases with radiotherapy.

In early selected cases surgery should be the treatment of choice, and Dr. Meigs described four different types of procedure that could be carried out: (*a*) radical panhysterectomy with pelvic-node dissection; (*b*) pelvic-node dissection only, as described by the late F. J. Taussig, where the cervical tumour was adequately controlled with radiotherapy; (*c*) extraperitoneal lymph-node dissection as described by Dr. Ira T. Nathanson; and finally (*d*) pelvic exenteration, as performed by Dr. Brunschwig. A number of patients with advanced tumours had no lymph-node involvement, and these were suitable subjects for pelvic exenteration. This type of surgery demanded great skill; not more than one in twenty surgeons was competent for work of this sort.

Mr. Victor Bonney recalled that for forty years he had championed the surgical treatment of carcinoma of e cervix. With regard to Dr. Brunschwig's account, felt that the removal of the bladder along with the erus was better than the old operation ; the removal the rectum as well was largely experimental, but is modification should be tried and judged on its sults.

Prof. Subodh Mitra (Calcutta) described his well-nown technique of radical vaginal hysterectomy. e agreed that this did not deal with the lymph-nodes d added that he had recently combined this operation ith an abdominal approach in order to remove the odes.

Prof. J. Heyman (Stockholm) expressed disbelief at there was any such thing as a radioresistant tumour. e was perfectly satisfied with the 42% absolute five-ear cure-rate he had achieved in the Radiumhemmet.

Dr. Malcolm Donaldson believed that the cell-count chnique described by Dr. Glucksmann was accurate ; e suggested that for the investigation of this and other roblems a clinical cancer research committee should e set up without delay by the Royal College of bstetricians and Gynæcologists.

Mr. Stanley Way undertook to show Professor Ieyman at least one radioresistant tumour at Newcastle. f a 42% cure-rate was satisfactory, what incentive was here to treat the remaining 58%, and what hope could hese patients ever expect ? He believed that the most uitable case for Wertheim's hysterectomy was also the nost suitable for treatment with radium. The lymph-odes were involved in nearly 70% of the radio-ncurable cases on which he had operated, but in less han 10% of the radio-curable group. He believed that adium would cure about 25% of cases ; and that another 0% could be saved by surgery and another 5% by the nassive pelvic exenteration described by Dr. Brunschwig. For the remainder there did not seem to be much hope t present. He supported Dr. Donaldson's plea for a ommittee to guide clinical cancer research because ardly anything was known about the natural history of carcinoma of the cervix.

Dr. Ninian Falkiner was convinced that radio-esistant tumours did exist ; and he showed microscopic pecimens from a case on which he had operated after full course of radiotherapy. These specimens showed ctive tumour in all parts, and he reasoned that uch a method of preserving specimens as he described hould be included in the cancer research programme.

Dr. Crosby (Montreal) believed that a further 6% of his early cases could have been saved by surgical intervention after radiotherapy.

MATERNAL MORTALITY

At this meeting the chair was taken by Dr. E. Chalmers Fahmy. The subject was introduced by Sir William Gilliatt, who referred to the Minister of Health's remarks on the recent improvement in mortality figures and deplored the Minister's use of these figures for political purposes. Sir William attributed the lowered mortality to the introduction of chemotherapy and improved technique in preventing sepsis ; but he admitted that with post-abortion sepsis the improvement was not so satisfactory, and he appealed for better facilities for dealing with this sort of case. The price of freedom from sepsis was eternal vigilance. The reduction in deaths from toxæmia was largely due to improved antenatal work ; and those who undertook antenatal care should also be responsible for the delivery of their patients. Routine weighing was as important as routine measurement of the blood-pressure ; and any increase of weight beyond 3 lb. in a week should be regarded as pathological. Hæmorrhage was still the greatest direct or indirect cause of maternal death, and it contributed very largely to both sepsis and embolism. The treatment of placenta prævia was nowadays more conservative ; active intervention should consist only of artificial rupture of the membranes and the use of a binder, or cæsarean section ; he personally favoured the lower-segment operation. He supported the use of oxytocic drugs before the uterus was empty in the third stage. The prevention of pulmonary embolism was most important, and he recommended exercises within twenty-four hours of delivery, but, in order to prevent prolapse, he preferred to keep patients in bed for fourteen days. The anæsthetic risks were enhanced in midwifery by the risk of inhaling vomit ; this was because opportunities to prepare the patient for an anæsthetic were often inadequate, and he regarded the provision of a specialist anæsthetist who could give his whole time to obstetrical work as a very necessary improvement in maternity departments.

Prof. Hilda Lloyd urged that normal confinements should be conducted by midwives, whose training fitted them better for the task than, for example, newly qualified doctors with no resident hospital experience in obstetrics. With regard to figures for Birmingham, she spoke of the immense value of the flying-squad in reducing deaths from hæmorrhage.

Dr. Percy Stocks, as a statistician, discussed the remarkable fall in both the obstetrical and the non-obstetrical deaths from sepsis in the past twenty years ; the fall had begun even before the era of the sulphonamides, so clearly some further factor was at work. He reckoned that about three-fifths of the fall in maternal mortality from sepsis was due to chemotherapy, and the other two-fifths to improved technique.

Prof. Dugald Baird appealed for closer coöperation between clinician and statistician. He spoke of the improvements in north-eastern Scotland ; but he was still not satisfied with the figures for shock, and he thought that a maternal mortality of 0·5 per 1000 was well within our compass within the next few years.

Sir Eardley Holland referred to his work for the Ministry of Health in investigating maternal deaths at the beginning of the late war. The most important cause of death was shock, with or without hæmorrhage ; and at least half the deaths could be prevented by applying quite ordinary standards of midwifery. He regarded the contribution of the Ministry of Health as insignificant. He recommended that maternal-mortality committees be set up, as in the U.S.A., and suggested that the Ministry should cooperate in this.

Mr. G. W. Theobald spoke of the influence of factors outside the maternity service and paid particular tribute to members of the public who acted as blood-donors. He thought that the fall in the death-rate from toxæmia was due to diet more than anything else. He referred to the abuses which he considered inherent in Ministry regulations which encouraged general practitioners to undertake midwifery that would otherwise have been left in the hands of competent midwives ; it would be a sorry day when we allowed anything to lower the status of the midwife, the backbone of the country's obstetrical services.

Dr. H. R. McLennan also deplored the inducement which the Ministry of Health gave to inexperienced general practitioners to undertake obstetrical work for which they were neither trained nor suited.

In closing the congress the President said that there had been over seven hundred registrations ; and he welcomed a hundred visitors from overseas.

OSLER CENTENARY CELEBRATION AT OXFORD

FROM A CORRESPONDENT

If an attempt were made to celebrate the anniversaries of all Oxford's famous men, the university would be in continuous fête. Yet it was right that the centenary of Sir William Osler's birth on July 12 should be commemorated, not only to keep his memory green but because no-one had a greater enthusiasm for commemorative feast days than Osler.

It was very different weather from that summer in 1905 when Dr. and Mrs. Osler and Revere first arrived, and scandalised north Oxford by lighting fires after the spring-cleaning. As we walked up Norham Gardens, past no. 7 where they first stayed, the grass of the parks was yellow and parched and the red geraniums in the lodge at the corner looked almost cool. The "Open Arms," 13, Norham Gardens, was left by Sir William to the governing body of Christ Church as a residence for subsequent regius professors; but none of them has lived in it, and since Lady Osler's death it has been used as a residential hostel for the students of St. Anne's. It seems a pity that it is not associated with the medical school, even though it may be too large for a modern regius; for there is much of Osler about the house—book-cases everywhere; three empty panels over the library mantelpiece where Linacre, Harvey, and Sydenham looked down on countless students admiring the books laid out to fire their enthusiasm for the history of medicine; the rather sombre consulting-room where Dr. Francis and Mr. Hill worked for nine years completing the *Bibliotheca Osleriana* before that wonderful collection, much of which was kept upstairs in the white-painted study which has still Osler's built-in desk with its red baize cover, went to McGill; the beautiful drawing-room with its sliding doors and the maple fireplace brought from Lady Osler's old home; the terrace overlooking the garden that Lady Osler loved. But it is nearly ten o'clock and instinctively one turns into Woodstock Road to reach the Radcliffe Infirmary; it has changed greatly and architecturally not for the better; the outpatient block still stands as it did, with the laboratories which Osler never failed to visit and which he helped Dreyer and Gibson to design; but the kitchens where he would taste the puddings and the children's wards where he was so welcome have altered beyond recognition. However by the Observatory stands an 18th-century house, once the home of the observer and now Osler House, where the clinical students have their common-rooms and library and Osler's portrait welcomes them in the hall; he would approve of Osler House.

It was natural to go to the Bodleian to look at Osler's clock and the Turbutt Shakespeare he helped the university to regain; then up Headington Hill to the Manor House estate where the new hospital will be built, probably in the time of the thirtieth regius, to judge from present activities; but this is a perlustration of the past, and though the Radcliffe Infirmary only purchased the estate in the last year of Osler's life, yet the Osler Pavilion, of which Lady Osler laid the foundation-stone in 1925, stands as a memorial to Sir William's work in the field of tuberculosis, and, for those who can read the hieroglyphics on its walls, as a reminder of the harm and delays that may come when medicine and local politics get mixed.

From Headington, we took the wandering country lanes along the valley of the Thame, and soon were passing the watercress beds in the waters of the spring from which Ewelme takes its name. Since 1617, the regius professor of medicine has been master of the almshouse, founded two centuries earlier by Alice, Duchess of Suffolk, and both Sir William and Lady Osler took a great interest both in the thirteen beadsmen and the village itself. The children were running out of Dame Alice's school—the only elementary school held in a 15th-century building—as we came along the lower road and passing the 18th-century parsonage reached the church, to find it open to the sky and heavy with the smell of cuprinol; death-watch beetle was found in its fine roof some twelve years ago and the work of preservation was delayed by the war. In spite of the scaffolding and the dust-sheets over the screen, it was impressive in the simplicity of the stonework and the magnificence of the font cover and the great tombs. From the west door a flight of well-worn steps leads to the quadrangle of the almshouse with its master's lodging, where Osler used to stay for a little peace and to be with his old men; it was cool and restful on this hot July day and it was not hard to believe that the thirteen almsmen found themselves in sympathy with the philosophy o *their master.*

The official ceremonies began in the afternoon and had been arranged by the Oxford division of the British Medical Association, which was very right, for Osler was a great supporter of medical meetings, and it was at the annual meeting of the association held in Oxford in 190 that he decided that he would accept the regius chai if invited. The chairman of the division, Dr. W. F Hudson, and the organising committee had shown brilliant insight in the selection of the speakers, for in their different ways they characterised the two major aspects of the Osler tradition—the textbook and the man. Sir Henry Cohen spoke on "subacute bacteria endocarditis: a study in the changing pattern of disease induced by modern therapy." After recounting the part which Osler played in the recognition of bacterial endocarditis, likening him to an English Morgagni, Sir Henry delivered a masterly clinical lecture on the disease calling attention to little-known early signs such as superficial thrombophlebitis or the occurrence of amenorrhœa in the mitral stenotic with menorrhagia; but the major portion of his address dealt with the effect of penicillin therapy, which he felt should be used more generously than is usually recommended; and he gave a warning against the use of a "penicillin umbrella" to ward off minor infections. From his carefully studied series of cases it was possible to say that with adequate treatment at least 50% of patients are "cured," bu he emphasised the complications that might become apparent—exacerbations of rheumatic heart disease vascular lesions often the residua of mycotic aneurysms and congestive cardiac failure which usually arose in those patients who had shown signs of failure before treatment had been instituted. Sir Henry concluded by pointing out that by prolonging life one was increasing the hazards of the disease and he spoke of the pleasure that Osler would feel in knowing that a practical and effective therapeutic agent, in a disease which in his day was invariably fatal, had been evolved in Oxford.

Lieut.-General Sir William MacArthur selected for his theme: "Of the smallpox: a review in the Osler tradition." Those who have heard Sir William lectur can imagine something of the artistry with which he wove his tale. Starting with the two occasions on which he met Osler, Sir William spoke of his indebtedness to the textbook: by quoting Rhazes and Sydenham he had successfully impressed examiners with an erudition which was really Osler's; by using the textbook to convince his commanding officer that chickenpox is rarely fatal in adults he had been able to avert a smallpox epidemic in an island garrison; and by finding that Osler had already made all the observations which he thought were original he had been saved from writing some papers. From there Sir William traced the history of smallpox in Great Britain, proving by a lucid etymological argument, which involved quotations from the *Annals of the Four Masters* and other early Gaelic literature, that the medieval epidemics of leprosy were in reality smallpox: he spoke of the origin of the epidemics of syphilis in the Renaissance; of the incidence of smallpox in the days of the Stuarts; of how the wicked Barbara Villiers [illegible] in favour because she had had the cowpox; [illegible] f "La Belle Stuart"; and of the [illegible] daughter. Then he talked of the other great mortality of the 17th century—the plague; of the children playing at plague burials in the streets, and how he had found the explanation for an unusual case in the writings of Ambroise Paré. And so the tale owed on, effortless and natural, without a note, without hint of pompous erudition, just as the other Sir William, nother Celt, used to talk in his library, of which Sir lifford Allbutt wrote: "to get at the flow of his nowledge and experience he had to be aroused by some opic in which he was specially interested; then in the nimation of talk he would bring forth things both new nd old."

In the gardens of the Radcliffe Observatory, recently aved from hut disfigurement, tea was served and the Regius Professor had a display of fine photographs of Ewelme in Osler House to remind us of the mastership nd of the "Friends of Ewelme Church" who are iving and collecting donations for the restoration und.

Recently the Radcliffe Science Library have been organising exhibitions in the history of science, and it was natural that the committee should select "Sir William Osler" for the present exhibition, which remains on view until December. On the walls of the staircase are panels with photographs and legends illustrating Osler's life and works in all its facets; and portraits of his *friends*—*Sir Thomas* Browne, Locke, SS Cosmas and Damian, and the original Acland triptych of Linacre, Harvey, and Sydenham. In the show cases are some of Osler's books, from the *early* works on diatoms to the *Evolution of Modern Medicine*; Egerton Y. Davis is there too, though he wears a figleaf; then the *Bibliotheca* is displayed with some of the manuscripts Osler gave to Bodley and a case is devoted to Osleriana.

The commemorative dinner, which over 250 attended, was at Christ Church, where Osler was a student—the equivalent of a fellow in other colleges—and found such pleasure in the common-room life, even though he was always forgetting that he might introduce only two guests. Before we entered the hall we went into the library to look at Robert Burton's library, gathered together by Osler, and forming a frame for his portrait—a very Oslerian touch which has been copied by other libraries. After the loyal toast Dr. Hudson read a telegram of greeting from the Osler Club of London, and then Prof. J. A. Ryle proposed The Art and Science of Medicine, speaking of the part which Osler had played: this was followed by Sir Hugh Cairns who proposed the toast of Sir William Osler and gave a delightful sketch of Osler as seen through the eyes of a young Australian Rhodes scholar and a disciple of Harvey Cushing. Prof. A. D. Gardner, the regius professor, proposed The Guests: and they were a notable gathering—the Mayor, the pro-Vice-chancellor, the President of Trinity; Dr. Peyton Rous; Captain Bachulus representing the American Embassy; Prof. Arthur Ellis, until recently regius professor; R. H. Dundas and Eric Gray of Christ Church and Prof. Sidgwick, an honorary student; Sir Lionel Whitby, regius professor of physic at Cambridge; Sir Arthur MacNalty; and Professor Bucy of Chicago. Lord Nuffield could not come, but Sir Hugh Cairns recalled that Osler's car was one of the last that Lord Nuffield had repaired with his own hands. In the hall were many who had known Osler well, such as Dr. A. G. Reade, who was a house-officer at the Radcliffe in 1907, and Dr. William Stobie, who was closely associated with Osler in the early and highly successful Oxfordshire tuberculosis dispensary scheme before it was stopped by the dead hand of bureaucracy; but many must have felt sad that Dr. A. G. Gibson, who knew Osler more intimately than anyone during his time at Oxford, could not be there to speak of the man he knew and loved. Dr. Peyton Rous replied for the guests and spoke as a former intern at Johns Hopkins.

As we descended the stairs from the hall, enjoying the fine stone vaulting, and then gathered in groups in Tom Quad to gaze at the fairy-like silhouette which long summer evenings give to the Oxford skyline, there must have been many who resolved to look again at the *Text Book*, *An Alabama Student*, or the *Evolution of Modern Medicine*, or perhaps to re-read Harvey Cushing's *Life*. So was Osler's birthday observed at Oxford and endorses his words: "In the continual remembrance of a glorious past, individuals and nations find their noblest inspiration."

In England Now

A Running Commentary by Peripatetic Correspondents

WHEN you drive through a village and see an ox looking out of a first-floor window, you may know you have really left England. When you meet other oxen wearing long fringes over their eyes and drawing wagons, you may be sure you have come south. And when the background composes itself of vineyards, extinct volcanoes, and monuments to Vercingetorix, you can be certain you have reached the Auvergne.

Do not suppose, however, that our life is barbaric: beside my bed is a choice of four bells for summoning four separate officials, including the cellarer. Moreover at every town our medical delegation is received with a ceremony that would be embarrassing were it not so charming. A few flags; a great many introductions: M. le Maire; and a simple banquet lasting two hours. In future I shall take care to wear my hat when leaving railway stations, in case the police force is standing at the salute when, amid photographers, we emerge. But our hosts have one gesture at least that leaves me incapable; so it is just as well that I don't have to make the speeches. It doesn't matter at the theatre, where one need do no more than stand respectfully in one's box; but yesterday, when we stopped in a little spa to take tea, I was badly shaken when the four musicians struck up "God Save the King," followed by the Marseillaise.

It is true that understanding is difficult when one's neighbour dilates on the amenities of English resorts of which one has never heard, such as Isborn: and I get absurdly conflicting answers to simple natural-history questions, such as whether there are still beavers in France. But none of our party will ever doubt again the reality and the value of an Entente that has become so much more than just cordial.

* * *

In those long minutes which I spend waiting for TOL, TRU, or O to answer in the evening, my eyes idly scan the information Messrs. Churchill provide in the two volumes of the *Medical Directory*. By the time that I have learnt the number of children's hospitals there are in Warwickshire, or the number of knights which the profession claims, I have forgotten the telephone number a harassed operator demands. But the time though wasted is not ill-spent. For the "local lists" stimulate memories of tiny villages which I have passed through or mushroom towns I hope I may hereafter avoid. They recall moor or hill, fen and lock over which I have wandered or sailed blissfully free of all Mr. Edison's contraptions.

If I wish for real escape it is to the counties of Sutherland and Ross that I go: if I wish for the freedom of imagination I can look them up in the *Medical Directory*. It at once strikes me that these areas are apparently under-inhabited and over-doctored. I can imagine why there are four doctors at Strathpeffer—it is or was a spa, though otherwise tiny enough—but I cannot think that Gairloch requires a similar number and I don't count those "*not in practice*." Some more tiny spots boast almost as many, and the reason is that these lists include, I am sure, the recently qualified Scot before he leaves these isles to explore the Empire.

If you go to these wild districts in the summer—some only to be approached by boat or antediluvian mail bus—you will find few young men or women. The men are the backbone of the Navy or the fishing fleet, and the older children are at the secondary school for the district, sixty miles away, boarding with distant relations. An astonishing number are at the university, or in the summer vacation adding to their income by many methods. If your sons or daughters (and there are many women in these lists) wish to practise in these parts they must learn more than is tested by the universities or Scottish colleges. They must be prepared to do rounds on a motor-cycle (despite recent pronouncements of the Minister) and even ride on horseback to lonely farms for confinements. They must not only be prepared to use a motor-boat but know something of the dangers of the sea lochs. They must care and continue to care for cases which cannot be taken to hospital by one ambulance only but whose transport may be a matter of rowing-boat, steamer, and motor ambulance. And they must know Gaelic. The number of people in Scotland who can talk no English is now very small. But when it comes to ministering to children in pain, or to the old in distress, it is in Gaelic that the sufferers will complain, and in Gaelic that the soothing words are spoken.

* * *

Last time I had seen the anæsthetist we had been drinking gin at my house. Last time I had seen the surgeon we had been drinking gin at his house. We had all been listening to the seductive voice of a French singer. My husband and the surgeon had been deeply moved. They had played the record again and again, refilling their glasses and thinking masculine thoughts. The surgeon's very sweet wife and I darned, unmoved by any emotion. Doctors' wives must remain calm no matter what the provocation—it helps their over-worked husbands.

Well, here I was on a stretcher trying to keep calm, for it looked as though the A. and the S. aforesaid were about to carry me to the theatre. Behave as for a first night: You're not enjoying it. No, neither are they. It's 4 A.M. Remember you trust them. Your feet are at an angle. Your head's in the surgeon's belly. It's him they ought to worry about; he must have steady hands. *Aren't there any porters in this place? No,* it's a spivvy nursing-home. Here's matron in a red belt. Couldn't I walk? I don't like this. I like the surgeon's red braces. Funny my life is in his hands—and in his brain. Why have I been reading Jean-Paul Satre? Never read Satre before operation. Step by step. Here we are. How hard the table is. The anæsthetist's gown is only tied in one place. "Lift up your head," he says. If only I'd had time to wash my hair. The surgeon is washing his hands. "Now for a nice sleep," the anæsthetist says in that Teddy Bear way that makes them famous. How my tummy hurts. Hurry up, do. I know, I've had it before. "Just a prick!" How bright these lights are. I don't even have to count. *The surgeon looks over his shoulder and grins. He's* got his cap thing on. I remember that he paints pictures and is mad on boats. I remember that they are both friends as well as doctors. The anæsthetist smiles and holds my hand. How does he do it? There's a bottle thing between us. Never mind, I haven't made a fuss. I hope I haven't got to do anything any more. I can sleep. It's up to them. . . .

And, so far as I am concerned, back to bed.

* * *

"Don't talk to me about the State Medical Service," said the local postmistress; "I just haven't got a doctor now." And she told me her story. It appears that she got a large piece of grit in the eye and went to the surgery. After 3½ hours in a well-attended waiting-room the secretary came in to say that the doctors were not coming today and everyone dispersed. Next evening she made a further visit and told the secretary that she must be seen quickly as her affairs did not permit of such leisurely attention. The doctor came in and asked her what was the matter; she told him. He said "You must have your eyes tested." She expostulated that all she wanted was to have the grit removed from her eye. "No, my dear, I can't possibly do that now but here is a form for you to have your eyes tested." Further *expostulation seemed* hopeless so she left and went to see the district nurse, who removed the offending particle.

* * *

So sweet-rationing is coming back next month. I'm sorry. Life is full of things we must or ought to do—like buying the 5*s.* 3*d.* insurance stamp each week, keeping our dangerous drugs registers up to date, getting the kitten "doctored" before it is three months old, returning library books in time—and it was a relief to feel that we need not buy exactly a pound of sweets every month. I know in theory it wasn't necessary to use the coupons, but in practice finding February's Personal Points in one's pocket when March had dawned caused a real feeling of guilt.

I told my young friend George about this and he has offered to send me a postcard reminder before the end of each rationing period in return for half the proceeds.

Letters to the Editor

HOSPITAL ADMINISTRATION

SIR,—Everyone concerned with hospital administration will thank you for dealing so fully with the very serious effects on hospital management of Ministerial control. Unfortunately the rigidity of central control is reinforced by the political faith of both the Socialist and Conservative parties. The old traditional English method of local government with central regulation broke down under the stress of war, and an increasing amount of direct central direction was introduced at that time. It has persisted in the new Education Act and in the National Health Service Act itself. In the hospital services, despite clear statements in the Act about the responsibility of boards for their actions, the boards are more and more coming to be regarded as the agents of the Ministry.

The Minister himself has repeatedly stated his desire to delegate as fully as possible powers to regional boards and boards of governors. Your proposal, that both these bodies should have power to spend their incom according to their best judgment, is the only way tha the freedom of hospitals to develop can be preserve I would add two footnotes to the proposals, which consider essential if the full value for locally determine expenditure is to be obtained for patients.

First, the insistence on a national scale of remuneratio for services rendered must go. Its results are unbelievably stupid. Because charwomen in hospitals are pai on a national scale, one hospital situated in an area city offices must go dirty whereas another in a differen district is cleaned seven days a week. Nurses go to th most attractive hospital because the money is the sam everywhere. *Radiographers go to country* hospita because living is cheaper. There are many mo instances. For example, the limitation of doctors certain fixed grades cannot fit the great variatio required for the efficient running of hospitals; and th *limitation will often cause reduction* in the number doctors employed simply because the total of the medica salaries will be considered too high. A managemen committee or board of governors with control of a income based on beds occupied would have to adjust it expenditure to get the best service it could, havin regard to local circumstances.

My second point is that the Ministry itself must lear discipline in the moments it chooses to add, quite casually, financial burdens to hospitals honestly trying to be helpful. Quite irresponsibly, when all expenditure has been planned and allowed for, it writes to add a few thousands here and several hundreds there by some statement on new salary scales, by some instruction on the closing of pay-beds, by a letter adding to the list of appliances to be provided for patients. All these additional burdens, however worthy, must be planned to fit an annual expenditure which the local committee controls. *I will admit that, in my own hospital, some* of these letters have been accompanied by a statement that a supplementary grant to cover the proposed expenditure will be favourably considered; but this is a very subtle threat, for it adds to the control which i already centralised too much. The Ministry cuts the estimates submitted by those who know local needs, and supplements in ignorance of local needs for such items *as seem good to it. This dangerous* course undermines local management still further.

It is tragic, when the hospital services are being moulded to a shape they will keep for years, that our profession should be devoting so much of its time, quite understandably, to trying to secure the personal future of its members. Only the doctors can appreciate how much is at stake in hospital management. Because it is omething so infinitely more important than individual ontracts of service. I am grateful to you for your lead.

CHAIRMAN.

SIR,—Thank you for your leading article of July 9. I am afraid that what you state is only too true.

The original intention was for the regional boards to be responsible for policy and planning of the hospitals within the region, and nothing else. What have they done in this respect? Surely they should now be taking steps to see whether the hospitals are large enough in structure and staff, and properly equipped to deal with patients. Instead they ask the management committees to inform them what extensions they consider essential in the next financial year. Where is the policy? Where is the planning?

The regional board should be planning for the hospitals in their region for ten years ahead. The plans should be prepared now and put into effect year by year so that at the end of the ten years the plans and policy for the period would be effected as a whole. Instead they appoint finance officers, supplies officers, and many others, who naturally wish to show that they are trying conscientiously to earn their salary: and thus they come to interfere with the management committees who have their own finance officer and supplies officer.

The Ministry has recently issued a circular on central purchasing. Why was this not done at the commencement of the new health service before supplies officers were appointed up and down the country? Personally I do not favour central purchasing, as it gives no initiative to management committees to have views of their own. It will tend too much to make all the hospitals' equipment to be standardised, with no originality or consideration for the needs of the patients in each area; instead it will bring all hospitals to the old workhouse standard of giving each patient the same kind of night attire, bedstead, mattress, locker, face-flannel, and soap—treating one and all as a mass of human beings, never minding what they feel about it or from what kind of homes they come. It is well that the management committees have agreed to form an association, which can speak with one voice to the Ministry of Health and see to it that the regional boards do not take from them the functions for which they were originally appointed.

Controlling expenditure by budgets and making each hospital keep within its budget, after it has been slashed by the regional boards and the accountant-general and his colleagues, is just a farce. How does any hospital know what kind of treatment will be required for its patients over a given period? Each hospital in preparing its budget would work largely on its expenditure for the previous year, but the weather, the various complaints from which the patients suffer, and other unforeseen circumstances may alter the whole financial estimate. If every contingency were allowed for, the budget would be at least 20% more than was spent during the previous year. This would allow the accountant-general to slash the budget by 10% and thus help him to feel he had done his job, leaving 10% for the hospital to have in hand for unforeseen circumstances. Is this what the Ministry wishes to be done?

In my young days as a hospital administrator I kept a detailed account of the cost of surgical dressings used in each surgical ward. At the end of each month I laid before the ward-sisters these particulars. On one occasion one ward cost very much more than the others, and the explanation was that during the month there had been an extra number of cases suffering from severe burns. How would the Ministry deal with this increased expenditure under budget control?

Heaton Moor, Stockport. HERBERT J. DAFFORNE.

LIVER EXTRACTS IN PERNICIOUS ANÆMIA

SIR,—Early this year you published some interesting letters on this subject. I would like to draw attention in particular to Dr. J. F. Wilkinson's of Feb. 5 and to your publication during the following weeks of the Oliver-Sharpey lectures delivered by him at the Royal College of Physicians in March, 1948. The main points of clinical importance he discussed were: the questions of adequate dosage and the potency of British liver extracts; the occurrence of relapses; and the early recognition of the signs of neurological involvement. The necessity for clinical trial before the issue of each batch of extract was stressed as the only reliable criterion of its potency, since microbiological assay and paper chromatography cannot yet replace it.

It is with reference to the potency of the liver extracts manufactured by our British chemists that I think it worth while to submit my personal experience. I do so as a physician who has the unsolicited advantage of suffering from pernicious anæmia. I have tested on myself the liver extracts made by four of our best known manufacturing chemists and in each instance I have found, over the past few years, a considerable variation in their potency based on such irrefutable evidence as the alleviation of symptoms and the maintenance of fitness for activity and work. It was therefore something of a shock to learn, from so high an authority as Dr. Wilkinson, that this variation in potency is due to the fact that our manufacturers, for a number of years, by the direction of the Ministry of Food, have been unable to obtain an adequate allocation of healthy and fresh calf or cow liver, and that they have had to use "so-called pharmaceutical livers—*i.e.*, livers unfit for human consumption which had been rejected in the abattoirs on account of disease."

For myself, I have been fortunate to obtain as a gift from relatives in the U.S.A. a supply of liver extract made by a leading American firm, after I had failed to purchase it in London. The results have left no doubt as to the superior potency of the American product. I wrote recently to the Ministry of Health drawing their attention to these facts, and asking, since this liver extract was not procurable in England, if I could be granted a permit to purchase the small quantity I required directly from America until fresh and healthy liver was made available to our own manufacturers. I will quote the main relevant points in the Ministry's reply.

> "I regret that we are unable to issue a permit for you to obtain liver extract from America. For over six years now, no such imports have been permitted and we have found no reason to alter this ruling. As you can realise, there have been many protests about this, and complaints that patients have not responded to British extracts. We have advised a trial of some other English firm's products (and there are several of these) and in *every instance* the doctor has made no further complaint. We have recently had a special committee looking into the allegation that the liver used for making British extracts is of too low a grade, and the committee could find no evidence that this was so. It is, of course, admitted that some patients responded better to one extract than to another, and that there is, from time to time, some variation between different batches of the same product; comparison of the vitamin-B_{12} content of British and American commercial extracts showed that the American ones had no advantage over our injectable liver extracts."

I understand from another source that this "special committee" was composed of representatives of the Ministry and of some of the commercial houses, and on such meagre information no judgment is possible of either the competency or the disinterestedness of this committee.

In your issue of July 2 you publish a letter from Sir William Dalrymple-Champneys, of the Ministry of rowing-boat, steamer, and motor ambulance. And they must know Gaelic. The number of people in Scotland who can talk no English is now very small. But when it comes to ministering to children in pain, or to the old in distress, it is in Gaelic that the sufferers will complain, and in Gaelic that the soothing words are spoken.

* * *

Last time I had seen the anæsthetist we had been drinking gin at my house. Last time I had seen the surgeon we had been drinking gin at his house. We had all been listening to the seductive voice of a French singer. My husband and the surgeon had been deeply moved. They had played the record again and again, refilling their glasses and thinking masculine thoughts. The surgeon's very sweet wife and I darned, unmoved by any emotion. Doctors' wives must remain calm no matter what the provocation—it helps their over-worked husbands.

Well, here I was on a stretcher trying to keep calm, for it looked as though the A. and the S. aforesaid were about to carry me to the theatre. Behave as for a first night. You're not enjoying it. No, neither are they. It's 4 A.M. Remember you trust them. Your feet are at an angle. Your head's in the surgeon's belly. It's him they ought to worry about; he must have steady hands. Aren't there any porters in this place? No, it's a spivvy nursing-home. Here's matron in a red belt. Couldn't I walk? I don't like this. I like the surgeon's red braces. Funny my life is in his hands—and in his brain. Why have I been reading Jean-Paul Satre? Never read Satre before operation. Step by step. Here we are. How hard the table is. The anæsthetist's gown is only tied in one place. "Lift up your head," he says. If only I'd had time to wash my hair. The surgeon is washing his hands. "Now for a nice sleep," the anæsthetist says in that Teddy Bear way that makes them famous. How my tummy hurts. Hurry up, do. I know, I've had it before. "Just a prick!" How bright these lights are. I don't even have to count. The surgeon looks over his shoulder and grins. He's got his cap thing on. I remember that he paints pictures and is mad on boats. I remember that they are both friends as well as doctors. The anæsthetist smiles and holds my hand. How does he do it? There's a bottle thing between us. Never mind, I haven't made a fuss. I hope I haven't got to do anything any more. I can sleep. It's up to them. . . .

And, so far as I am concerned, back to bed.

* * *

"Don't talk to me about the State Medical Service," said the local postmistress; "I just haven't got a doctor now." And she told me her story. It appears that she got a large piece of grit in the eye and went to the surgery. After 3½ hours in a well-attended waiting-room the secretary came in to say that the doctors were not coming today and everyone dispersed. Next evening she made a further visit and told the secretary that she must be seen quickly as her affairs did not permit of such leisurely attention. The doctor came in and asked her what was the matter; she told him. He said "You must have your eyes tested." She expostulated that all she wanted was to have the grit removed from her eye. "No, my dear, I can't possibly do that now but here is a form for you to have your eyes tested." Further expostulation seemed hopeless so she left and went to see the district nurse, who removed the offending particle.

* * *

So sweet-rationing is coming back next month. I'm sorry. Life is full of things we must or ought to do—like buying the 5*s.* 3*d.* insurance stamp each week, keeping our dangerous drugs registers up to date, getting the kitten "doctored" before it is three months old, returning library books in time—and it was a relief to feel that we need not buy exactly a pound of sweets every month. I know in theory it wasn't necessary to use the coupons, but in practice finding February's Personal Points in one's pocket when March had dawned caused a real feeling of guilt.

I told my young friend George about this and he has offered to send me a postcard reminder before the end of each rationing period in return for half the proceeds.

Letters to the Editor

HOSPITAL ADMINISTRATION

SIR,—Everyone concerned with hospital administration will thank you for dealing so fully with the very serious effects on hospital management of Ministerial control. Unfortunately the rigidity of central control is reinforced by the political faith of both the Socialist and Conservative parties. The old traditional English method of local government with central regulation broke down under the stress of war, and an increasing amount of direct central direction was introduced at that time. It has persisted in the new Education Act and in the National Health Service Act itself. In the hospital services, despite clear statements in the Act about the responsibility of boards for their actions, the boards are more and more coming to be regarded as the agents of the Ministry.

The Minister himself has repeatedly stated his desire to delegate as fully as possible powers to regional boards and boards of governors. Your proposal, that both these bodies should have power to spend their income according to their best judgment, is the only way that the freedom of hospitals to develop can be preserved. I would add two footnotes to the proposals, which I consider essential if the full value for locally determined expenditure is to be obtained for patients.

First, the insistence on a national scale of remuneration for services rendered must go. Its results are unbelievably stupid. Because charwomen in hospitals are paid on a national scale, one hospital situated in an area of city offices must go dirty whereas another in a different district is cleaned seven days a week. Nurses go to the most attractive hospital because the money is the same everywhere. Radiographers go to country hospitals because living is cheaper. There are many more instances. For example, the limitation of doctors to certain fixed grades cannot fit the great variations required for the efficient running of hospitals; and this limitation will often cause reduction in the number of doctors employed simply because the total of the medical salaries will be considered too high. A management committee or board of governors with control of an income based on beds occupied would have to adjust its expenditure to get the best service it could, having regard to local circumstances.

My second point is that the Ministry itself must learn discipline in the moments it chooses to add, quite casually, financial burdens to hospitals honestly trying to be helpful. Quite irresponsibly, when all expenditure has been planned and allowed for, it writes to add a few thousands here and several hundreds there by some statement on new salary scales, by some instruction on the closing of pay-beds, by a letter adding to the list of appliances to be provided for patients. All these additional burdens, however worthy, must be planned to fit an annual expenditure which the local committee controls. I will admit that, in my own hospital, some of these letters have been accompanied by a statement that a supplementary grant to cover the proposed expenditure will be favourably considered; but this is a very subtle threat, for it adds to the control which is already centralised too much. The Ministry cuts the estimates submitted by those who know local needs, and supplements in ignorance of local needs for such items as seem good to it. This dangerous course undermines local management still further.

It is tragic, when the hospital services are being moulded to a shape they will keep for years, that our profession should be devoting so much of its time, quite understandably, to trying to secure the personal future of its members. Only the doctors can appreciate how much is at stake in hospital management. Because it is omething so infinitely more important than individual ontracts of service. I am grateful to you for your lead.

CHAIRMAN.

SIR,—Thank you for your leading article of July 9. I am afraid that what you state is only too true.

The original intention was for the regional boards to be responsible for policy and planning of the hospitals within the region, and nothing else. What have they done in this respect? Surely they should now be taking steps to see whether the hospitals are large enough in structure and staff, and properly equipped to deal with patients. Instead they ask the management committees to inform them what extensions they consider essential in the next financial year. Where is the policy? Where is the planning?

The regional board should be planning for the hospitals in their region for ten years ahead. The plans should be prepared now and put into effect year by year so that at the end of the ten years the plans and policy for the period would be effected as a whole. Instead they appoint finance officers, supplies officers, and many others, who naturally wish to show that they are trying conscientiously to earn their salary: and thus they come to interfere with the management committees who have their own finance officer and supplies officer.

The Ministry has recently issued a circular on central purchasing. Why was this not done at the commencement of the new health service before supplies officers were appointed up and down the country? Personally I do not favour central purchasing, as it gives no initiative to management committees to have views of their own. It will tend too much to make all the hospitals' equipment to be standardised, with no originality or consideration for the needs of the patients in each area; instead it will bring all hospitals to the old workhouse standard of giving each patient the same kind of night attire, bedstead, mattress, locker, face-flannel, and soap—treating one and all as a mass of human beings, never minding what they feel about it or from what kind of homes they come. It is well that the management committees have agreed to form an association, which can speak with one voice to the Ministry of Health and see to it that the regional boards do not take from them the functions for which they were originally appointed.

Controlling expenditure by budgets and making each hospital keep within its budget, after it has been slashed by the regional boards and the accountant-general and his colleagues, is just a farce. How does any hospital know what kind of treatment will be required for its patients over a given period? Each hospital in preparing its budget would work largely on its expenditure for the previous year, but the weather, the various complaints from which the patients suffer, and other unforeseen circumstances may alter the whole financial estimate. If every contingency were allowed for, the budget would be at least 20% more than was spent during the previous year. This would allow the accountant-general to slash the budget by 10% and thus help him to feel he had done his job, leaving 10% for the hospital to have in hand for unforeseen circumstances. Is this what the Ministry wishes to be done?

In my young days as a hospital administrator I kept a detailed account of the cost of surgical dressings used in each surgical ward. At the end of each month I laid before the ward-sisters these particulars. On one occasion one ward cost very much more than the others, and the explanation was that during the month there had been an extra number of cases suffering from severe burns. How would the Ministry deal with this increased expenditure under budget control?

LIVER EXTRACTS IN PERNICIOUS ANÆMIA

SIR,—Early this year you published some interesting letters on this subject. I would like to draw attention in particular to Dr. J. F. Wilkinson's of Feb. 5 and to your publication during the following weeks of the Oliver-Sharpey lectures delivered by him at the Royal College of Physicians in March, 1948. The main points of clinical importance he discussed were: the questions of adequate dosage and the potency of British liver extracts: the occurrence of relapses; and the early recognition of the signs of neurological involvement. The necessity for clinical trial before the issue of each batch of extract was stressed as the only reliable criterion of its potency, since microbiological assay and paper chromatography cannot yet replace it.

It is with reference to the potency of the liver extracts manufactured by our British chemists that I think it worth while to submit my personal experience. I do so as a physician who has the unsolicited advantage of suffering from pernicious anæmia. I have tested on myself the liver extracts made by four of our best known manufacturing chemists and in each instance I have found, over the past few years, a considerable variation in their potency based on such irrefutable evidence as the alleviation of symptoms and the maintenance of fitness for activity and work. It was therefore something of a shock to learn, from so high an authority as Dr. Wilkinson, that this variation in potency is due to the fact that our manufacturers, for a number of years, by the direction of the Ministry of Food, have been unable to obtain an adequate allocation of healthy and fresh calf or cow liver, and that they have had to use "so-called pharmaceutical livers—i.e., livers unfit for human consumption which had been rejected in the abattoirs on account of disease."

For myself, I have been fortunate to obtain as a gift from relatives in the U.S.A. a supply of liver extract made by a leading American firm, after I had failed to purchase it in London. The results have left no doubt as to the superior potency of the American product. I wrote recently to the Ministry of Health drawing their attention to these facts, and asking, since this liver extract was not procurable in England, if I could be granted a permit to purchase the small quantity I required directly from America until fresh and healthy liver was made available to our own manufacturers. I will quote the main relevant points in the Ministry's reply.

> "I regret that we are unable to issue a permit for you to obtain liver extract from America. For over six years now, no such imports have been permitted and we have found no reason to alter this ruling. As you can realise, there have been many protests about this, and complaints that patients have not responded to British extracts. We have advised a trial of some other English firm's products (and there are several of these) and in *every instance* the doctor has made no further complaint. We have recently had a special committee looking into the allegation that the liver used for making British extracts is of too low a grade, and the committee could find no evidence that this was so. It is, of course, admitted that some patients responded better to one extract than to another, and that there is, from time to time, some variation between different batches of the same product; comparison of the vitamin-B_{12} content of British and American commercial extracts showed that the American ones had no advantage over our injectable liver extracts."

I understand from another source that this "special committee" was composed of representatives of the Ministry and of some of the commercial houses, and on such meagre information no judgment is possible of either the competency or the disinterestedness of this committee.

In your issue of July 2 you publish a letter from Sir William Dalrymple-Champneys, of the Ministry of

Health. This attempts to refute clinical experience that British liver extracts made from pharmaceutical livers are inferior to those made from "fresh edible livers." He says: "Though no detailed evidence was offered *in support of this view, it was nevertheless decided* to inquire into the matter. . . . In the discussions which have been held here no evidence could be discovered to substantiate the claim that better liver extracts could be made by using fresh, edible livers than by using so-called 'pharmaceutical livers.'" This is a remarkable statement. As points worth noting he defines "pharmaceutical livers" as "a trade term to cover livers which are tough or not sufficiently fresh in appearance to attract the housewife. It does not include tuberculous livers, or those with abscesses or cysts, or other obvious disease . . ."; adding, with a touch of unconscious humour ". . . and such livers are not used for the manufacture of liver extract." He assures us that "in any case the production processes provide effective sterilisation." This is a consummation devoutly to be wished! As to his remarks on the variation in potency, I can only again stress that clinical experience is the only reliable test, and it is by this criterion that our British products have shown in recent years their relative inefficiency.

In face of the clinical evidence, it is regrettable that the material necessary for producing a liver extract of reliable potency is not made available to our British chemists, or, if this cannot be done, that permission to purchase the present more reliable American products is still being withheld. The amount of dollar exchange involved would be relatively insignificant where the well-being and the lives of our patients are concerned.

Clevedon, Somerset. C. W. EWING.

THE APPEALS

SIR,—Your editorial note to the letter of July 9 under this heading makes sad reading. Surely the editor of a scientific journal should not misquote for the purpose of strengthening an argument; neither the writer of the letter nor anyone else has suggested that existing appointments should be *automatically* confirmed. But what matters chiefly is that you should support the downgrading of hundreds of doctors who for years have worked as specialists to the satisfaction of their patients and colleagues, and complacently suggest they should sell their houses, abandon their friends and patients, and wander the face of the country on a series of interviews in search of fresh fields—for that is what you are propounding.

Before and since the coming of the Act there has been constant mention of the shortage of specialists, and now you approve their further curtailment. In response to any outside criticism you would doubtless stoutly defend the doctors of Britain as amongst the best in the world; could you then, Sir, also defend your opinion that very large numbers, and apparently in some areas a majority, of those previously known and practising as specialists are not fit to retain their appointments?

Finally, it is hardly honest to argue that a S.H.M.O.—a man whose title shows that he has already been assessed as not fit to be a consultant—should, in competition for a consultant post, "most certainly be under no disability compared with a trainee specialist."

The patient comes first, and has always done so; but this does not mean that he only is to be considered. The secretary of the B.M.A. recently read a paper on the relationship of happiness to health. You, Sir, should study it; it cannot be applied to the patient alone. One had hoped, with slowly diminishing faith, that an efficient (which must mean also a happy) service could be built up out of the Act. To uproot large numbers of specialists from localities in which they have serve faithfully for years—you imply this is the corollary the policy you advocate—in pursuit of some chair-born fetish of "tidiness" will certainly not make for a happ profession. The scientific side of your journal magnificent. One could wish that the non-scientifi was unbiased.

Royal West Sussex Hospital,
Chichester.

C. J. HARWOOD-LITTLE.

*** We have never advocated that specialists shoul be required to join in a kind of general post in order be upgraded. On the contrary, on June 4 we wrot "What is required is a mechanism whereby the status men in all but the most senior grade can be reviewed recognised intervals, *even though they seek no chang* of post or place." We still think that this should an can be assured. Even when such a procedure is opera tive, there will still be men in the S.H.M.O. class who wi apply for posts that attract them elsewhere, and w believe that, as presumably many of them are no classified as S.H.M.O. while they acquire greater experienc and more mature judgment, their future application f senior posts should be given unbiased consideratio The post should go to the most suitable candida irrespective of his previous grading.—ED. L.

MEDICAL RESEARCH COUNCIL OF *IRELAN*

SIR,—In your note on the annual report of the Medica Research Council of Ireland (July 2, p. 26) the followin sentence appears: "*Four or five tuberculous* sinuse healed satisfactorily after short treatment with B.53. It might be understood from this statement that the was some uncertainty about the number of sinuse treated. The sentence in the original report shoul have read: "Four of five tuberculous sinuses . . The succeeding sentence, however, removes all ambiguit It reads: "The fifth sinus had dried and was progressi favourably at the latest report."

VINCENT C. BARRY
M. L. CONALTY.

University College, Dublin.

THYROTOXIC EXOPHTHALMOS WITH MYOPATHY

SIR,—Dr. Strong's article of June 4 prompts me describe a case *in some ways closely resembling the o* he reports.

A man, aged 62, was admitted to hospital complainin of attacks of hoarseness and dysphagia at intervals for abou five years. For the last ten weeks the difficulty in swallowing and the hoarseness had persisted. The patient also described a prominence of his left eye, becoming progressively worse during the past six years, together with failing vision i that eye. His general health was then fairly good althoug he had lately been losing weight. He had had genera lassitude for the past twenty years, and about twenty year ago a diagnosis of thyrotoxicosis was made by hi private doctor, although the evidence upon which thi diagnosis was made is not known.

On examination there was prominence of both eyes, bu much more of the left. There was moderate œdema of th upper lid of the left eye. The pupils reacted well to light bu the left optic disc was very pale. The thyroid gland wa not palpable, and his pulse-rate was about 80 per min. and regular. The patient weighed some $8^1/_2$ stone. Clinicall he was not suffering from thyrotoxicosis. Examination of th central nervous system was negative, as also was examinatio of the abdomen, heart, and lungs. His blood-pressure wa 150/100 mm. Hg. Laryngoscopy showed paralysis of the lef vocal cord, *which was fixed near to the midline.*

Investigations.—Basal metabolic rate: + 17%. X-ray examination of chest: enlarged hilar glands, but otherwise normal. Cerebrospinal fluid (C.S.F.): normal. X-ray examination of skull: negative. Kahn test in blood and C.S.F.: negative. Electrocardiogram: normal. Blood-count: Hb 84%; red cells 4,220,000 per c.mm.; colour-index 1·0; mean orpuscular volume 97 cμ; mean corpuscular hæmoglobin oncentration 30%: white cells 7500 per c.mm. (neutrophils 5%, lymphocytes 18·5, monocytes 6·5%).

It is considered that this case was one of thyrotropic xophthalmos with chronic myopathy. The myopathy nd exophthalmos seemed to have developed in parallel. he relapsing nature of the myopathy is of interest, and oes seem to support its thyrotropic ætiology—associated ossibly with variations in the rate of release of hyroid-stimulating hormone.

I wish to thank Dr. R. E. Horsfall for permission to report his case.

Victoria Hospital, Blackpool. RAYMOND C. GLEDHILL.

ANTI-HISTAMINE DRUGS IN THE TREATMENT OF BURNS

SIR,—A few days before I read the letter of May 28 from Dr. Shubsachs, my son—13 years old and very fair—swam for some hours in a pond exposed to the sun. When he came home he looked very ill, and he was red all over. He had no fever, but the dermatitis was very severe and painful. I applied 'Inotyol' ointment followed by free dusting with talcum powder. The burning was partly relieved but he was unable to sleep at night. I gave him one capsule of 'Benadryl' (50 mg.): he felt better and was sound asleep in about half an hour. He took three capsules daily, and dusted himself several times a day with talcum powder. On the fourth day he was cured completely and was able to attend school again.

This confirms Dr. Shubsachs's opinion that anti-histamines may have an important rôle in the treatment of burns and even other inflammations of the skin.

DJAMIL FAÏK TUTUNJI
Amman, The Jordan. Under-Secretary of State for Health.

HÆMOLYTIC DISEASE OF THE NEWBORN DUE TO ANTI-A ANTIBODIES

SIR,—In your issue of June 25 Miss Boorman and her colleagues reported two cases of hæmolytic disease of the newborn due to anti-A. They pointed out that the most convincing evidence of the action of anti-A in such cases is the demonstration that A cells, but not O cells, are rapidly destroyed after transfusion. In one of their cases they succeeded in securing evidence of the rapid elimination of A cells, though they could not obtain serial quantitative data. A little while ago we obtained satisfactory estimates of the survival of A and O cells in a similar case, and this may be an opportune moment to record them.

The mother had had one previous pregnancy, resulting in a healthy child (later shown to be group A_1). Her second infant was born two years later. Before its birth the midwife noticed that the liquor amnii was very yellow and at birth the infant's umbilical cord was yellow and the vernix caseosa orange. A sample of blood was obtained from the umbilical vein immediately the child was born, and this had a hæmatocrit of 30% and a hæmoglobin concentration of 10 g. per 100 ml. (These values are only about 60% of the average normal and are far below the normal range.) The serum-bilirubin concentration was 3 mg. per 100 ml.—just above normal limits for cord blood; and a blood film showed a considerable excess of nucleated red cells. The direct Coombs test was weakly positive.

The results of blood-group tests were as follows:

Infant.—A_1 (secretor), MN, CDe/cDE: its serum did not agglutinate A or B cells suspended in saline.

Mother.—O, MN, CDe/CDe; her serum hæmolysed A cells but not B cells; the serum had an iso-agglutinin titre of 1/1000 against A_1 cells and of 1/128 against B cells. The titres were no higher when the cells were suspended in 30% albumin and the serum was diluted in albumin than when the titrations were done in saline. The serum did not agglutinate, or sensitise to an anti-globulin serum, cells of types CDe/cDE or cde/cde.

The bloods of the mother and infant were also tested by Dr. Sylvia Lawler of the M.R.C. Blood Group Research Unit who found that both were P+, S−, Lewis+, and Kell−; the mother was Lutheran-negative and the infant Lutheran-positive, but the mother's serum did not contain anti-Lutheran.

By 16 hours after birth the infant's hæmoglobin concentration had risen to 16·4 g. per 100 ml., doubtless mainly owing to the placental transfer of blood; the serum-bilirubin level was 5·5 mg. per 100 ml. and the reticulocyte-count 8·6%. The infant was transfused via the umbilical vein with about 35 ml. of washed, packed O, N, CDe/CDe cells and 40 ml. of washed, packed A_1, M, cde/cde cells. With very potent anti-Rh and anti-M sera, counts could now be made of the survival of the A_1 and the O cells. Venous samples were taken from scalp veins on succeeding days and the estimates were:

Time after transfusion	Unagglutinated erythrocytes per c.mm. *		Total Hb (g. per 100 ml.)
	O cells (with anti-M)	A cells (with anti-Rh)	
Before	4000	4000	16·4
10 min.	853,000	1,030,000	18·9
1 day	873,000	968,000	19·4
4 days	880,000	545,000	18·4
5 days	932,000	396,000	17·7
6 days	901,000	352,000	17·2
11 days	935,000	216,000	15·5
20 days	765,000	234,000	14·1
47 days	566,000	113,000	12·6

* Each estimate based on a count of approximately 3000 cells.

Thus during the six days after transfusion the concentration of transfused A cells fell to about 35% of the initial value. By contrast, during the same period the count of O cells actually rose slightly, probably because of a readjustment of blood-volume. Evidently the survival of the O cells was normal and that of the A cells grossly reduced. The increased rate of elimination of A cells came to a stop between 6 and 11 days after birth; and by the end of the first week of life the reticulocyte-count had fallen to 1·5%.

The direct Coombs test remained definitely positive for 48 hours after birth, was doubtfully positive 5 days after birth, and thereafter was negative.

The infant's progress was entirely satisfactory.

MARIE CUTBUSH.

EXCHANGE OF DOCTORS WITH THE U.S.A.

SIR,—Before the war there were some schemes in action for the exchange of doctors between hospitals in this country and the U.S.A. There is now a more widespread desire by doctors in this country to visit the U.S.A. This may often be facilitated by arranging for a regular exchange of doctors between medical schools and hospitals in the two countries.

There seems to be some fear that making such an arrangement for an American doctor to work in a hospital here infringes the Acts governing medical practice. This is not the case, for by section 8 of the Medical Practitioners and Pharmacists Act, 1947, Parliament has made provision for the admission to the Medical Register of Commonwealth and foreign practitioners temporarily in the employ of hospitals in this country.

If a hospital is prepared to offer a postgraduate post to a qualified practitioner who is not registered here, it is desirable both for him and for the hospital that he should have the status of a registered medical practitioner as the holder of that post; and section 8 enables him to become temporarily registered for that purpose.

The procedure for temporary registration under the section is quite simple, and it is only necessary to add that a practitioner who is not a British subject must, of course, as a first step obtain permission from the Home Office to enter and to remain in the U.K. in order to do postgraduate work.

R. C. MAC KEITH
Guy's Hospital, London, S.E.1. Hon. Secretary, The Horse Shoe Club.

MALLEOLAR FRACTURES

SIR,—In his article of July 9, Dr. Herzog did well to emphasise the importance of inversion as a cause of fracture of the external malleolus.

In work as yet unpublished I have found that fractures of the external malleolus unaccompanied by other fractures or by dislocations fall into four groups.

1. A complete fracture with minimal displacement, appearing in the lateral view as an oblique crack extending up and back from the anterior cortex at joint-level to the posterior cortex $^{3}/_{4}$ in. above joint-level, and in the anteroposterior view as a line running up and out from joint-level.
2. A transverse fracture below joint-level and about $^{1}/_{2}$ in. above the tip of the malleolus, the separation being wider at the outer end.
3. A fracture of the tip of the malleolus.
4. A fracture of the fibula above joint-level but extending to within 1 in. of the ankle-joint, the fracture-line running up, out, and back.

In my series there was no group of transverse fractures at joint-level. A single case of this type did occur, and in contrast to all the other cases it was due to direct violence. On the other hand it is common experience that transverse fractures at joint-level occur in association with fractures of the internal malleolus. It follows then that the nature of the indirect violence which will produce a transverse fracture at joint-level is such that it must also break the internal malleolus or ligament. This combination of injuries occurs in the "2nd-degree abduction type" of malleolar fractures or in the "follow-through" injury[1] mentioned by Herzog. In my series all but three of the cases of isolated fractures of the external malleolus due to an indirect violence the nature of which was recorded, were due to an inversion strain. Inversion does not, therefore, cause a transverse fracture at joint-level. This is produced only by abduction or by the "follow-through" injury (which is virtually abduction), and then only in association with a lesion of the internal malleolus or ligament.

This is indeed what one should expect on considering the mechanics of the two strains—inversion and abduction. On forced inversion the talus begins to tilt when the limit of subastragaloid movement has been reached, and the strain is on the external ligament and the lower end of the fibula. This strain will either rupture the ligament, pull off a fragment of the malleolus, or, using the lower edge of the tibia as a fulcrum, bend the lower part of the fibular shaft and crack it above joint-level. In abduction there is a horizontal outward movement of the talus which causes simultaneously a direct impact against the external malleolus and a pull on the internal malleolus and the internal ligament—a dual action which produces a dual lesion.

Of 41 cases of isolated fractures of the external malleolus in which the nature of the indirect violence was described by the patient, all but 3 were due to an inversion strain. Now it is generally accepted that fractures of types 2 and 3 are due to an inversion strain. But type 1, an oblique fracture of the external malleolus running up from joint-level, corresponds to what is often described as a "first-degree external-rotation injury." Yet this was the commonest of the four types (about 66%), and no case of external-rotation strain was recorded in the series. The conclusion that the type 1 is no exception to the rule that all fractures confined to the external malleolus are inversion injuries, is reinforced by the following points.

(a) Inversion strain is by common experience the most frequent indirect violence to which the ankle is subject. The most common *bony* injury due to indirect violence affecting the ankle is fracture of the external malleolus, and of such fractures type 1 is the most frequent.

(b) An external-rotation injury involves a violent twist of the astragalus, so that the anterior part of the outer edge of the superior articular surface hits the anterior margin of external malleolus synchronously with the impact of posterior part of its inner edge against the posterior margi the internal malleolus. It is difficult to conceive that viol of this nature would result in a single bony injury.

(c) Cases of type-1 injury are sometimes associated cases of type 2 and type 3 which are undoubtedly du inversion.

Thus fractures of the external malleolus consequ on indirect violence and unassociated with other b or complete ligamentous injury in the region of a are due to an inversion strain, and this conclusion d not except the oblique fracture running up from jo level which is more often attributed to an exter rotation injury.

With regard to "eversion" as a factor in the prod tion of malleolar injuries, I do not believe this to important. It is prevented from acting on the talus the downward projection of the external malle along the whole depth of the talus. The short inte malleolus on the other hand is not a barrier to inver of the talus.

LOCATION OF RENAL PAIN

SIR,—In view of the various theories about visc pain which have been upheld in your columns, I wo like to report the following case.

A girl of 15 complained of right-sided abdominal pain; on examination the pain was found to be localised to the ri loin. There was tenderness in the right costophrenic an and slightly in the left costophrenic angle. Pus cells *Bact. coli* were found in the urine, and right-sided a pyelitis was diagnosed.

Subsequently, however, intravenous and retrograde py grams showed that the right kidney was on the left side, below the left kidney; its ureter crossed the midline in lower lumbar region, and turning downwards entered bladder at the normal site.

Thus at the site where the pain was felt and wl most of the tenderness was elicited, there was in no kidney. This illustrates that where the pain is depends on the nerve-supply and not on the positio the viscus in which it is produced.

London, N.W.1. E. M. POULTON

COMPLICATIONS OF PARA-AMINOSALICYLIC ACID THERAPY

SIR,—Since *p*-aminosalicylic acid (P.A.S.) is be increasingly used in the treatment of tuberculosis, seems worth recording our experience of its undesira effects in two patients.

CASE 1.—A male musician, aged 40, had had bilateral act pulmonary tuberculosis diagnosed in January, 1947, a several months' failing health and productive cough. He had 20 months' rest in bed before admission to Colindale August, 1948.

On admission he was fairly ill with moderate fever, sev cough, and 7 oz. of sputum daily. A chest radiogram sho two giant cavities in the left upper lobe and old disease the right lung. The symptoms were greatly relieved keeping the patient resting on his left side, with the foot his bed raised 10 inches. Six weeks later a routine ch radiogram showed "atelectasis" of his left lung, and a so focus taking the place of one cavity. Bronchoscopy sho a normal bronchial tree. The symptoms returned only af attempts at re-aerating the left lung. Two months lat in December, 1948, sodium *p*-aminosalicylate 6 g. twice da was given. There was again improvement in the gene condition and considerable relief of symptoms. Twenty-f days later the patient became acutely ill, with mala anorexia, nausea, headache, and intense photophobia, fev and physical restlessness. The cerebrospinal fluid showed abnormality, and a chest radiogram no apparent chan 'Benadryl' 100 mg. two or three times a day appeared give some relief.

After a further week it became apparent that there were cute exacerbations of symptoms, starting about 10 min. fter the giving of a dose of P.A.S. Particularly prominent at his stage was the patient's complaint of intense generalised kin irritation (apart from scratch marks no rash was seen) nd a ceaseless violent non-productive cough. Subsequently he patient told of his fear to close his eyes, because of bright ashes of vivid colours. Withdrawal of P.A.S. produced almost mmediate relief of symptoms. Later, mild symptoms—mainly kin irritation and cough—were caused by as little as 0·25 g. f P.A.S. An intradermal injection of 0·05 g. did not produce ny skin reaction. All blood and urine examinations have een normal. At no time was a high level of P.A.S. detected n the blood.

This seems to be a true case of acquired idiosyncrasy to P.A.S., the explanation of which is not apparent. The light suppressive action of benadryl suggests that a ocal liberation of "histamine-like" substances may have been one of the factors involved. The patient gave no history suggesting allergy. The sodium *p*-aminosalicylate was made up freshly on alternate days, from powder supplied by the manufacturers, in 2 oz. of water flavoured with a few minims of liquorice. Neither before nor after the event did the patient show any sensitivity to salicylate in the form of aspirin or other compound tablets.

CASE 2.—A male motor mechanic, aged 26, had had active pulmonary tuberculosis diagnosed in December, 1945, after radiography of his chest because of pain in his back. The film had shown a limited lesion in the left lung.

On admission to Colindale in March, 1946, the disease had extended locally and spread to the opposite lung. Treated on routine lines in bed his condition had improved sufficiently for a left artificial pneumothorax to be attempted in July, 1946; this was found to be contra-selective and was abandoned. No further active treatment was attempted till September, 1947, when an anterior stage thoracoplasty was done as a preliminary to inserting a drainage tube into a giant cavity, to be followed by a posterior thoracoplasty. In October, 1947, the patient was found to have proteinuria and an enlarged liver. Amyloidosis was diagnosed and subsequently confirmed by liver biopsy; 6–10 g. of protein was excreted daily in the urine for the next twelve months.

A course of P.A.S. 12 g. daily in six doses was started in October, 1948, and continued for four weeks, during which time the urinary protein excretion increased to 20–30 g. daily. The urine also contained a few red blood-cells and numerous granular and hyaline casts, a few of which gave the congo-red reaction. Various urinary excretion tests all fell within normal limits. The blood-urea level remained normal, and the blood-proteins amounted to 5–6 g. per 100 ml.—average albumin 2·5 g. per 100 ml., and globulin 3 g. per 100 ml. There was no increase of blood-pressure. An occasional transient œdema was noted. After withdrawal of P.A.S. the urinary protein excretion slowly dropped and finally stabilised at about 10–12 g. daily. P.A.S. therapy produced no change in the patient's general condition or the radiological appearance of the chest.

Though there is no evidence that the diseased kidneys were irreparably damaged by P.A.S., it is certain that the glomeruli were affected in some way, allowing increased protein filtration, and for this reason it seems advisable to refrain from using P.A.S. where there is evidence of generalised disease of the nephrons. In some forty other patients treated with P.A.S. the only urinary abnormality detected has been the occasional presence of red blood-cells, and in none of these cases was it necessary to discontinue treatment.

Colindale Hospital, London. M. HEMMING
C. J. STEWART.

SIR,—During a recent therapeutic trial of *p*-aminosalicylic acid (P.A.S.) in rheumatoid arthritis, of 6 cases treated 5 developed hypoprothrombinæmia. Hæmorrhagic levels were not reached, but in 2 cases the prothrombin-index was reduced to 50% and 57% of normal, without any evidence of liver dysfunction. The dosage of the drug was 15 g. daily by mouth, given in 5 doses of 3 g. at three-hourly intervals. The prothrombin-times were estimated by the technique of Quick,[1] Fullerton's[2] 'Stypven' modification being used in 3 instances.

There is no mention of this effect of P.A.S. in reports on the use of this drug in tuberculosis, where higher dosage has often been given. This action, however, is well known to occur during the exhibition of other salicylates, and fatal hæmorrhages recorded in rheumatic fever may in part be attributable to these drugs. Unexpected hæmorrhages have been recorded recently in your columns by Nagley and Logg,[3] who had 5 cases of frank hæmaturia during the treatment of pulmonary tuberculosis with P.A.S. While there may be some doubt about the conclusion that the bleeding in these cases was due to crystallisation of the drug in the urinary tract, it is obviously undesirable for hæmorrhage to take place in the presence of hypoprothrombinæmia.

Department of Medicine, University of Edinburgh. J. NORRIE SWANSON.

MECHANICAL RESPIRATION

SIR,—Dr. Blackwell's article in your issue of July 16, though helpful in many respects, brings into prominence the deplorable absence of information, not only regarding the best types of respirator but also regarding the instructions which should be issued to those who—often unexpectedly—have to take charge of a patient with respiratory paralysis.

With regard to the nursing of the respirator case, an excellent publication on the subject can be obtained on request from the National Foundation, 120, Broadway, New York 5, N.Y. A lung inflator or resuscitator should also be available to maintain artificial respiration, so that the patient can be removed from the box without anxiety. Indeed short periods of artificial respiration with an inflator will sometimes be sufficient to tide over a period of respiratory distress. The type with a hand-operated valve is probably better than the McKesson type referred to by Dr. Blackwell, for the skilled operator can time the hand-operated valve to assist the patient's spontaneous effort to breathe. The Oxford inhaler referred to by Dr. Blackwell is much inferior to the Oxford inflator,* which is a highly efficient resuscitator.

Dr. Blackwell refers to a situation in which "the patient nearly dies if the machine is opened for more than a few seconds," but this will not occur with a suitable inflator. The patient can quickly become accustomed to a hand-operated inflator if it is used first (with accurate timing and at low pressure) while the patient is still in the respirator.

Dr. Blackwell concludes that the Stille is the best respirator available, but the evidence on which this conclusion is based is not clear. There is an obvious need for a small research unit, which should include a respiratory physiologist, to study the efficiency of respirators. Only by this means can we learn the relative advantages of the different makes.

Finally, a word about bulbar cases with secretions or perhaps vomit obstructing the larynx. These secretions must be removed by sucker and steep postural drainage at 30–40°. Use of the respirator in such an emergency is disastrous and usually causes death, since it forcibly sucks the secretions into the lungs. In bulbar cases, if the muscles of respiration are acting even weakly the respirator should be avoided, but the angle of postural drainage must be so steep that all fluids fall out of the pharynx. A tilting bed of the type used for bronchiectasis is useful for this type of case, and can incidentally be

* As supplied by Medical and Industrial Equipment, Ltd., 12, New Cavendish Street, London, W.1.

used for artificial respiration by the rocking method. If the muscles of respiration fail, the respirator must also be used; but postural drainage must be maintained in the respirator by tilting the box steeply, and a sucker should be at hand to maintain a free airway.

Oxford. W. RITCHIE RUSSELL.

EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—I would like to thank Dr. Sweetnam for his letter in your issue of July 16.

I think it is fair to say that some strains of poliomyelitis virus are inactivated by pasteurisation, while others are not. Much work on this subject has been done with the Lansing strain of virus which many American workers today consider to be unrepresentative. Conclusions based on such work may therefore not be valid. Incidentally, I should like to point out that I am not contesting the desirability of universal pasteurisation, which in fact I cordially support. I am merely concerned with the policy to be adopted in the face of an outbreak suspected to be spread by milk. Would it be sufficient to rely on pasteurisation? Personally I feel it would be safer to advise that the milk should be boiled.

The County Hall, London, S.E.1. G. E. BREEN.

SIR,—In this district shortly before and during the poliomyelitis season last year there was an unusual mortality amongst hedgehogs. Has such a coincidence been noticed in other districts? Is the hedgehog susceptible to poliomyelitis virus?

It is entirely premature to theorise about the hedgehog as a reservoir host or as a possible laboratory animal; but it may be worth while to experiment with it. "There is more missed by not looking than by not knowing." Laboratory workers who propose to experiment with them are warned that hedgehogs are very verminous animals; they cannot scratch themselves.

D. P. LAMBERT
Settle, Yorks. Divisional Medical Officer.

THE MENSTRUAL CYCLE

SIR,—Dr. Geiringer, whose views on the control of the menstrual cycle you published on July 9, is right that the importance of the adrenal cortex increases as new information about its functions becomes known. There is, however, no experimental foundation for his statement that "adrenal cortical hormones have as constant and decisive an influence in determining the events of the normal menstrual cycle as the pituitary and ovarian hormones"—unless one understands by this merely that the adrenal cortex is essential to life.

The fact is that the œstrous cycle stops after removal of either the pituitary or the ovaries. It does not stop after adrenalectomy provided salt is administered. This treatment may also restore menstrual function in a patient with Addison's disease who has amenorrhœa. Contrary to the implication in Dr. Geiringer's letter, there is no general agreement that amenorrhœa is a common feature of this disease. But since Dr. Geiringer suggests that I have underemphasised the importance of the adrenal cortex in the menstrual cycle, may I draw his attention to work[1] mentioned in my lecture which provides the most direct evidence that I know of for the view that this gland undergoes cyclical changes in relation to those which occur in the female reproductive organs. I do not, however, know whether this work has been corroborated.

It is well known that a variety of sex hormones can be extracted from the adrenal cortex; that disturbance of the production of these hormones will affect reproductive processes; and that the gonads and adrenal cortex are derived from adjacent parts of the embr These facts, however, in no way justify Dr. Geiring view that the adrenal cortex is "the mother-orga the gonads," or that it plays an important rôle in determination—a belief which, to the best of knowledge, has no scientific foundation.

Birmingham. S. ZUCKERMA

Parliament

QUESTION TIME

Grading of Hospital Medical Officers

Mr. V. J. COLLINS asked the Minister of Health if he w define the qualifications of a senior hospital medical o and the minimum qualifications of a consultant under National Health Service.—Mr. A. BEVAN replied: I shoul presume to do so. Each individual case needs judging o merits, by local professional committees suited to the Mr. COLLINS: Is the Minister aware that owing to the of information on this subject there is a great deal of confu and dissatisfaction? Does he not think that a stater would be helpful to all persons concerned?—Mr. BEV I cannot issue any general information on this matter. grade to which a doctor belongs is decided by a professi committee, and I have not the least intention of interfe with that committee. They decide each case on its me and I can do no more than leave the matter to the mem of the profession concerned.

Squadron-Leader E. L. FLEMING: Can the Minister whether, where a doctor has been demoted from a highe a lower grade, he has a right of appeal to anybody?— BEVAN: It is wrong to speak of demoting. This is the time that grading has been done; therefore there can b demoting from a superior to an inferior grade. There review of the initial decision, and arrangements have made to establish machinery for the purpose.

Advertising Appliances

Sir HUGH LUCAS-TOOTH asked the Minister whether he aware of the practice of commercial firms advertising their particular appliances could be obtained entirely fr charge under the National Health Service, and offerin names and addresses were sent to them, to advise applic of procedure; and whether he would introduce legislatio put an end to this practice.—Mr. BEVAN replied: Action already been taken to stop advertising in connexion hospital appliances, and similar steps are being considere cover appliances supplied through the National Health Ser

Rubery Hill Mental Hospital

Mr. A. R. BLACKBURN asked the Minister whether he completed his inquiry into conditions at Rubery Hill Me Hospital; and with what result.—Mr. BEVAN replied: questions in the House involved three main issues:

(*a*) The alleged wrongful certification of old people.
(*b*) The understaffing of Rubery Hill Mental Hospital.
(*c*) The circumstances attending the death of a patient at hospital.

The result of the inquiries on the first point is that, as not a single name has been forthcoming of any person could be shown to have been wrongfully certified under Lunacy Acts. The Ministry of Health deprecate the ce fication of old people if it can possibly be avoided and if h are available outside mental hospitals; and recommendati have been made to the regional boards in this matter. necessity for certification may arise in some cases becaus the moment the only suitable accommodation available i our mental hospitals; but no case has come to notice which a person certified was not of unsound mind.

Two officers of the Ministry of Health have visited Rub Hill Hospital and reported in detail on the nursing positi The female staff has recently increased by six, and act steps are being taken to stimulate recruitment. The inspect officers have made some detailed recommendations which be communicated to the management committee of hospital. In general, they found that the staff is prope controlled, that the administration of the hospital is go and that the staff work as a happy team.

The circumstances attending the death of a patient were ie subject of an inquest by the coroner sitting with jury. verdict of accidental death was returned, and the matter as dealt with in the debate on the adjournment of the ouse on June 3.

Free Clothes for Hospital Patients

Mr. HAYDN DAVIES asked the Minister to what extent it was is practice to provide free clothes for hospital patients.—Ir. BEVAN replied: I shall be glad to clear up the many ross misrepresentations on this matter. I have told hositals, in effect, to go on doing what was already proper iospital practice before the health service began—that is to end clothing to patients who cannot provide it for themselves r get it from any other agency, and to let them keep it on lischarge when inquiries make it clear that they cannot therwise get it. It will normally only arise, as in the past, or long-stay ambulant patients without resources.

Spectacles

In answer to a question, Mr. BEVAN stated that the total lemand for the United Kingdom in the first six months of 1949 was estimated at 5 million pairs. Production during the same period was about 3·7 million pairs, representing an increase of 75% on the annual rate of production during 1947. Production in this country continued to be rapidly expanded and suitable lenses were being imported from abroad.

Over-prescribing

Mr. PETER FREEMAN asked the Minister whether he was aware that much larger quantities of medicines were frequently supplied on National Health Service prescriptions than were necessary; and what steps were being taken to prevent such waste of public money.—Mr. BEVAN replied: A doctor whose prescriptions suggest extravagance may have his prescribing investigated by a local professional committee. Before this he would be given the opportunity of explaining his reasons to, and being advised by, one of my department's medical officers.

Central Purchase of Medical Stores

Mr. A. M. SKEFFINGTON asked the Minister of Health what economies had so far resulted from the centralised purchase of medical stores and equipment.—Mr. BEVAN replied: I regret that a precise estimate of savings on central purchase of medical stores and equipment for the National Health Service is not available. If I had to give a broad estimate I should say something like £2 million.

Compound E

Mr. A. R. BLACKBURN asked the Lord President of the Council, in view of the satisfactory evidence as to the efficacy of compound E in the treatment of rheumatic diseases, what steps were being taken through the Medical Research Council or other bodies to ensure the production of this drug on a large scale at the earliest possible date.—Mr. HERBERT MORRISON replied: Research aimed at finding effective new substances akin to compound E is in active progress under the Medical Research Council, but I am advised that all these compounds are exceptionally difficult to make and that early success is not to be expected. Large-scale production of compound E itself is a matter for commercial laboratories rather than the council, but here again the difficulty of synthesis must hamper speed, and I understand that the American manufacturers of the compound have intimated that it is unlikely to be generally available for use by doctors even in the United States for several years at least.

Dangers of New Insecticides and Fungicides

Mr. T. E. N. DRIBERG asked the Lord President of the Council whether he was aware of the large number of commercial insecticides and fungicides, containing dangerous poisons, now offered for sale to food-growers and smallholders; and what steps were taken by his department, in conjunction with the Ministries of Food and Agriculture, to test fully, and over a considerable period of time, the effects of these products on plants and on human beings.—Mr. HERBERT MORRISON replied: The Agricultural Research Council and the Medical Research Council are aware of the potential dangers of the indiscriminate use of some of the new insecticides and fungicides and there is a special toxicity subcommittee of the Research Coördinating Committee on Insecticides, a body appointed jointly by the Medical Research Council, the Department of Scientific and Industrial Research, and the Agricultural Research Council, which arranges for the examination of new materials. As to the effect of insecticides and fungicides on plants, active and continuing research is in progress at several agricultural research institutes. In regard to the effect on human beings, the Agricultural Research Council works in close collaboration with the toxicology committee of the Medical Research Council. The inquiries of that committee include long-term studies.

Pay of Army Nurses

Brigadier A. H. HEAD asked the Secretary of State for War whether he was satisfied with the present strength of the Queen Alexandra's Royal Auxiliary Nursing Corps; and when he expected to make an announcement regarding the new conditions of service and pay of this corps.—Mr. EMANUEL SHINWELL replied: The Army, like the civil hospitals, is having considerable difficulty in securing the services of nurses. The strength of the Queen Alexandra's Royal Army Nursing Corps is more than 900 below establishment, and civilian nurses are being employed as a temporary expedient. I hope that it will be possible for a statement on the new conditions of service to be made shortly.

Public Health

Cold Floors

IN his work, *The Physiological Basis of Medicine*, Graham Brown observed that long after the civilised world had adopted the habit of finishing a meal with coffee, the scientists came along to prove that it was good for digestion to do so. Scientists working in two separate departments of government-sponsored research have now proved similarly what we already know—that to the bare foot a concrete floor feels colder than almost any other.

For his observations on floors, N. S. Billington,[1] of the building research board of the Department of Scientific and Industrial Research, used an electrical "foot" consisting of a metal canister fitted with a thick, flat, copper base which is insulated on top and at the sides.

The temperature of the under-surface of the "foot" is measured by copper-constantan thermocouple wires attached to the base of the canister and connected to a sensitive galvanometer. Water—150 ml. at about 120°F—is placed in the canister and stirred continuously. The canister is allowed to cool on a slab of cork, and a cooling-curve is plotted. When the water temperature has fallen to 100°F the canister is quickly transferred to the specimen, and readings of the base temperature are taken at 10-sec. intervals for 2 min. and thereafter less frequently. The experiment may continue for 5–15 min. When the temperature of the water is 100°F, the base temperature is about 97·5°F.

In a second series of tests the base of the canister was covered with the sole of a shoe, about $^1/_4$ in. thick. The base temperature recorded still refers to the underside of the copper base and not to the surface of the "shoe."

Billington concludes that his experiments "lend support to the common belief that a concrete floor feels colder than a wooden floor at the same temperature: although, when shoes are worn, the difference due to the actual nature of the floor finish seems likely to be small." He recommends for places like bedrooms and bathrooms, where people are likely to be walking barefoot, floors of wood, cork tile, linoleum on wood, and carpets, but suggests that these types of floor (giving a sensation of warmth) are not so important for kitchens, offices, factories, and nurseries, "where people stand or sit for lengthy periods." This reference to nurseries is strange because it is standard practice amongst those who can afford it to have their nurseries at home covered whenever possible with cork linoleum so that the infant shall get no sensation of chill when it stands or crawls; Billington seems to think that this end could be achieved by placing underneath the "cold" material, which should be as thinly spread as possible, an insulating layer.

Munro and Chrenko,[2] of the Medical Research Council, have also been testing the effect of various flooring

---

1. Billington, N. S. *J. Hyg., Camb.* 1949, 46, 445.
2. Munro, A. F., Chrenko, F. A. *Ibid*, p. 451.

materials on "the thermal sensations and skin temperature of the feet"; in their experiments they have used not any artificial "feet" but the natural variety—their own. Some tests were made when their feet were bare, and others when they were shod with shoes of normal weight and medium thick soles over light-weight woollen socks. (This seems to represent considerably greater insulation than was used by Billington when his electrical "foot" was shod by a sole of only $^1/_4$ in. thickness.) As the primary aim of their investigation was to study the effects of different floor materials on the comfort of the feet, the subjects were seated throughout the test period, it being argued that the effects of the materials would be greatest under these circumstances, and that if people are moving about in a room with a concrete floor the effect of the floor on the thermal comfort of the feet is likely to be less than when they are seated. This argument, which seems reasonable enough, is in direct conflict with the views of Billington that cold floors are not of much moment to people who sit for lengthy periods.

The range of the observations by Munro and Chrenko was wider than Billington's, taking in the effects of air temperature and velocity as well as of the floor material in contact with the feet. But although these additional factors have a bearing on their results, they still agree with Billington that a cork floor generally is more "comfortable" than a concrete one. ("Comfort" is here used in a rather specialised, "thermal" sense.) Unlike Billington, who sought to reduce the chilling effect of cold floors by putting a layer of insulating material *under* them, the other two observers tried linoleum over concrete; they were disappointed in the result. They conclude that changes in the skin temperatures and in the sensations on the sole of the bare foot correspond approximately to the thermal conductivities of floor materials. They also explain why foot chill may seem more pronounced after exercise. When anyone sits down after exercise two factors, they say, may operate. There is less heat-production which may have the effect of reducing the central blood requirement and thus of increasing the peripheral supply. Venous stasis will be encouraged by diminution of the normal massaging action of the muscles on the blood-vessels, and this may induce a temporary rise in skin temperature. Heat may still be accumulating in the limb, since its skin temperature is low and the heat-loss may not exceed the heat produced within the limb or conveyed to it; hence the initial sensation of warmth. Very soon, however, the heat-inflow to the limb diminishes, and simultaneously, for the reasons already given, the skin temperature rises, so heat no longer accumulates at the previous rate and the sensation of warmth progressively diminishes. Finally, heat-dissipation exceeds heat-inflow and a progressive fall in skin temperature becomes associated with subjective feelings of cooling in the limb.

The *Eleventh Annual Year Book of the American Public Health Association*, for 1940–41,[3] contains an outline of air standards for the maintenance of comfort, health, and efficiency, assuming altitudes not exceeding 10,000 ft. above sea-level. These are: cool rather than hot (though avoiding a sense of chilliness); dry rather than damp; still or moving, depending upon physical activity; some diversity in temperature (rather than uniformity and monotony); and *foot level as warm as head level.* Munro and Chrenko themselves, linking their foot observations with general considerations of ventilation and metabolism, finally conclude that, assuming uniform conditions of heating, the air temperature is the dominant factor influencing the thermal comfort of the feet, but that there is a value of air temperature below which floors of high conductivity are undesirable.

Infected Milk in Yorkshire

We are indebted to Dr. D. P. Lambert, divisional medical officer, Settle, for the following information.

On June 30 this year, farm S, supplying school milk, was short of the required quantity and bought milk from farm D. The cowman at farm D had been ill with diarrhœa and vomiting during the week, but had said nothing and carried on with his work. It was hay-time; everybody was very busy. This consignment infected milk from farm D was stored overnight in refrigerator and distributed along with farm S milk schools in Settle rural district on July 1. On July 332 cases of food-poisoning occurred amongst sch children who drank milk from this consignment. Th were no cases in Skipton rural district, which unmixed milk from farm S, and no cases on farm retail milk-round. There were 3 mild cases on farm milk-round, and 2 moderately severe cases on the fa itself.

The symptoms were fever, headache, prostrati abdominal pain, vomiting, and diarrhœa. In mildest cases the symptoms were constitutional rat than abdominal, and were attributed at first to "a tou of the sun" or "teething." In the severer ca abdominal symptoms were more pronounced, a frequent stools were passed containing blood and muc Most cases were mild to moderate. There were deaths and no case was removed to hospital, thou some dozen probably would have been had this bee less rural area with hospitals nearer.

Salmonella typhi-murium was isolated from a case farm D, from a sample of the school milk for July from four out of six empty but unwashed milk bottl and from the stools of selected cases amongst scho children.

Poliomyelitis

In the week ended July 9 notifications were: pol myelitis 73 (80), polioencephalitis 4 (1). Figures for t previous week are shown in parentheses. Multiple cas (poliomyelitis and polioencephalitis together) we reported from: London 6 (6), Cheshire 2 (2), Cornw 5 (9), Devon 11 (4), Gloucestershire 3 (3), Hertfordsh 4 (3), Lancashire 5 (5), Middlesex 5 (9), Nottinghamsh 3 (0), Southampton 2 (1), Warwickshire 3 (1), Yorkshi West Riding 10 (9), Glamorgan 3 (1).

The general picture of incidence is very different fr that at the corresponding period in 1947. In 1947 early rise in incidence was chiefly in the more dens populated parts of central England, with additio foci in north-west Lancashire (Barrow) and on Tynesi This year, although there has been some rise of incide in the central parts, the chief increases have been in t west and south. Notifications in the West Riding Yorkshire have risen to 10 (9), but otherwise the no has remained remarkably free from the disease. T year, unlike 1947, there have been high attack-ra in relatively small and isolated communities.

Births, Marriages, and Deaths

BIRTHS

FOOTE.—On July 8, at Woking, the wife of Dr. E. S. Foote—a so

FOX.—On July 7, in London, the wife of Dr. D. G. R. Fox—daughter.

GILLESPIE.—On July 6, the wife of Dr. C. W. Gillespie—a daughter

HARPER.—On July 5, at Swindon, to Dr. Marita Harper (n Shattock), wife of Dr. Eric Harper—a daughter.

SHERRY.—On July 10, to Kathleen Robinson, F.R.C.S., wife Dr. Vincent Sherry—a daughter.

MARRIAGES

GIORDANI—HODGES.—On July 9, at Kingston-on-Thames, Aldo Giordani, M.R.C.S., to Christine Hodges, M.B.

WESTLAKE—WHITTON.—On June 29, at Alyth, Perthshire, Ern Keith Westlake, M.B., to Nora Whitton.

WRIGHTSON—PUMPHREY.—On July 9, at Halton, Bucks, Phil Wrightson, F.R.C.S., to Erica Prudence Pumphrey.

DEATHS

BROWN.—On July 13, at Gullane, East Lothian, Robert Archib Brown, M.B. Glasg., surgeon captain, R.N. retd.

CARRE-SMITH.—On July 11, in London, Herbert Lovell Carre-Smit M.R.C.S., aged 80.

COOKE.—On July 13, in London, Sir Douglas Cooke, M.B. Melb F.R.C.S., aged 70.

GOURLAY.—On July 15, at Rathmore, Elgin, Frederick Gourla M.D. Edin., aged 81.

JONES.—On July 11, at Beaconsfield, Lawrence Jones, M.S. Lond F.R.C.S.

MARSDEN.—On July 10, in Manchester, Richard Walter Marsde M.D., B.SC. Manc., F.R.C.P., D.P.H., aged 81.

RAIT-SMITH.—On July 11, at St. Albans, Brian Rait-Smith, B Camb., M.R.C.S., D.A., F.F.A.R.C.S.

SHACKEL.—On July 14, George Arthur Shackel, M.R.C.S., aged 8

WIGHT.—On June 22, at Dudley, George Douglas Wight, M.B. Edin D.P.H.

Notes and News

CENTENARY AT WESTMINSTER

THE centenary celebrations of Westminster Medical School ened at Church House on July 14, when Mr. H. M. Clowes, airman of the medical school committee and council, esided over a large gathering which included over 150 mer students, many of whom had travelled long distances an expression of their devotion. The Earl of Athlone, ancellor of the University of London, in his opening address pressed his gratification that although the school as part the university had its separate legal existence with its own uncil, its ties with the hospital remained as close as ever. though barely eleven years had elapsed since the present hool buildings were opened, there was already talk of new ildings with a preclinical school, and for this scheme of velopment he could assure those responsible of the support the university.

Sir Ernest Rock Carling (dean of the medical school 1909–12) called that although the school properly constituted was day celebrating its hundredth birthday, it had much longer aditions in the system of apprenticeship by which pupils ere attached to one man responsible for all subjects of their lucation. Even 100 years ago the hospital could already ast among its past staff 16 fellows of the Royal Society, presidents of the Royal College of Physicians, and 4 presints of the Royal College of Surgeons. For a time all bjects of the curriculum were taught and taught with the ghest efficiency, until the school's sphere was limited to the inical period through the recommendations of the Adami port and arrangements were made by the University of ondon for appropriate assistance at King's College. It was ght to think with gratitude first of those who gave their me, experience, and wisdom to the governance of the hool—Sir John Wolfe-Barry, Sir Robert Hudson, Sir dward Pearson, Sir Thomas Butler, Colonel Bulkeley, Mr. aux Graham, and many others ending with Mr. Kenneth olfe-Barry, without whose courage, supported by the uthority and prestige of Mr. Goodenough, we should not ow be in possession of either school or hospital. Among edical giants, great teachers as well as great clinicians, Sir rnest singled out from personal association Sir William llchin and Charles Stonham whom he believed to have been he real founders of the modern school. It was impracticable give a complete list. Among those he recalled as physicians ere Sir Bryan Donkin, Charles Mercier, de Havilland Hall, ir James Purves-Stewart, Sir Stanley Woodwark, Drummond obinson, and Hildred Carlill; as surgeons, A. H. Tubby, alter Spencer, William Turner, Arthur Evans, Tudor dwards, Stanley Dodd, and Arthur Griffiths.

Sir Adolphe Abrahams (dean of the medical school 1934–43) escribed the transformation effected by the migration from pathetic little building in Caxton Street to the present agnificent edifice. In contrasting the large with the small chool, he emphasised as a particular advantage of the small chool that its staff was necessarily recruited largely from utside its own students, and that when a vacancy occurred ompetition was thrown open to the whole world. The uccessful candidate brought to the school all the necessary ttributes and still more the traditions, the reputation, and he wisdom of other teaching institutions. The teaching taff now numbered more than fifty. Of these about a quarter ere Westminster's own sons—a remarkable proportion for o small a school. The remainder included representatives rom no fewer than eight of the other great metropolitan chools—from Edinburgh, Aberdeen, Dublin, Belfast, Liverool, Manchester, Birmingham, and Bristol, and from ustralia and New Zealand. Academically and in sport the tudents exhibited a keenness, a distinction, and a success hich were remarkable in regard to their numbers. Mr. G. H. acnab (the present dean) said there were now 230 students, he large majority taking university degrees. He described he difficulties relating to the proposed creation of a teaching entre with 1000 beds to provide facilities for 400–500 prelinical and clinical students. In addition it was necessary o keep undergraduate and postgraduate teaching in separate ompartments. He deplored the premature specialisation in cientific subjects demanded by competition. Only about ne in sixteen of those interviewed gained a place in the chool. Another complication was the influence of compulsory ational service in the Armed Forces for a boy but not for girl. He was dubious of the method of selection by a committee and believed a personal interview to be the supreme test, especially when opportunity was afforded for full consideration of the candidate's background. He was confident of Westminster's ability to provide the right training for the best type of doctor in the next century, as in the past.

LIVERPOOL RESOLUTION ON GRADING

AT a meeting of the Liverpool Regional Hospitals Medical Association on July 11, the following resolution was passed.

"This meeting regrets that, in spite of cases of upgrading, there are many anomalies still existing both with regard to groups and to individuals. We are particularly concerned about the two specialties venereology and tuberculosis, in which the grading has been almost uniformly that of senior hospital medical officer. We feel that low grading will inevitably have a depressing effect on efficiency in the future, since recruitment will fall in quality. Some of the individual grading seems to us so unjust that we feel that it is essential that fresh consideration to individual appeals should be given forthwith. We therefore heartily support the British Medical Association's claim for the setting up of regional appeal committees before which the appellant will have the right to appear in person and be represented."

RESEARCH IN EDINBURGH

IN the report for 1948 of the laboratory of the Royal College of Physicians of Edinburgh, Dr. R. Cranston Low, the curator, records that for the first time the annual number of reports on clinical material has exceeded 30,000. The 100, 1000, 10,000, and 20,000 marks were passed in 1891, 1898, 1925, and 1938; and the increase shows no sign of abating. In the research field, the relation between chemical structure and antimalarial activity is being investigated, and new derivatives of *p*-phenanthroline and 2:3-benzacridine have been synthesised. Benzthiazole compounds have been synthesised and are being tested for possible antifilarial activity. An analysis of the relations between chloride content and electrical conductivity in human milk has shown that both are abnormally high in mothers with an inadequate supply of milk. In the bacteriological department, Dr. W. M. Levinthal has continued typing smooth pneumococci; since 1942 more than 1000 strains have been identified.

ALCOHOLISM IN SWITZERLAND

Switzerland has extensive vineyards; and the average annual consumption of alcoholic drinks amounts to about 8 litres (compared with $4^{1}/_{2}$–5 litres in Great Britain), consumed mostly as wine. This was explained to the Society for the Study of Addiction on July 12 by Dr. Henri Revilliod, who estimated that the average Englishman drinks 4 times more beer but 100 times less wine than the Swiss. In Switzerland spirit-drinking, which had disastrous effects in the German-Swiss cantons during the 19th century, has been greatly reduced through the federal alcohol monopoly. The chief cause of alcoholism in French Switzerland is wine in the countryside and aperitifs in the towns, whereas in the German-Swiss cantons cider and spirits are more popular. In Switzerland cirrhosis of the liver is apparently more common than in any other country and is thought to arise chiefly from protracted mild alcoholism. Cirrhosis has been found at 11% of necropsies (14% of males, 7·5% of females); in 91% of the cases the condition was attributed to alcoholism, and very often the liver disorder had not been diagnosed during life.

Inebriates are treated at 75 centres—the "anti-alcoholic dispensaries"—and where necessary in homes for the rehabilitation of addicts (six for men, three for women). Since 1946 patients have been admitted to hospital in Geneva for treatment with apomorphine. Of 73 addicts psychologically normal or with some disorder due to alcoholism, 72% abstained from alcohol for three months, and 46% for more than two years after treatment.

Hospital Board Appointments

The Minister of Health has made the following medical appointments:

Oxford regional hospital board.—Prof. T. Pomfret Kilner, F.R.C.S., in succession to Prof. A. W. M. Ellis.

Eastman Dental Clinic board of governors.—C. F. Ballard, M.R.C.S., L.D.S.

National Hospital for Nervous Diseases board of governors.—Macdonald Critchley, F.R.C.P., in succession to Dr. J. Purdon Martin.

Hammersmith, West London, and St. Mark's Hospitals board of governors.—L. Comyns, L.R.C.P.E., M.P.

University of Cambridge

On June 21 the degree of M.D. was conferred on T. S. Hindle.

An Elmore research studentship has been awarded to Dr. D. R. Smith.

University of London

At a recent examination for the academic postgraduate diploma in public health the following were successful:

Abdulla Omar Abushamma, R. F. Barclay, Shriniwas Yeshwant 'sh, J. F. E. Bloss, L. B. De Lanerolle, Habib . E. G. Earle, L. G. Eddey, T. P. Eddy, S. J. , A. W. Gilks, A. H. Griffith, R. F. Guymer, W. G. Harding, C. H. Hoskyn, Esther Jackson, Shelly A. Jones, Wickramaratchyge Ajitha Karunaratne, Mohan Singh Kataria, D. A. Kuruppu, M. G. Langdon, P. A. Lee, R. N. C. McCurdy, J. C. McDonald, T. C. Macdonald, J. J. McNair, J. R. Mayers, Isobel S. Mowat, G. M. O'Donnell, C. E. Phillip, Isabella M. Pinkerton, J. St. C. Polson, R. H. Pratt, P. G. Roads, C. L. E. H. Sharp, R. A. G. Smith, D. G. Snell, W. B. Thorburn, R. N. Wilson.

University of Liverpool

At recent examinations the following were successful:

M.D.—C. V. Donnelly, J. G. P. Jones, Edith M. McConnell, P. L. Robinson, W. Sircus, A. H. Williams.

M.Rad.—(*Part I*) J. Ainsworth, Constance M. Davis; (*Part II*) J. F. Doherty, W. J. L. Francis, B. B. Harrison, W. Kulke, J. P. MacLaughlin, A. S. Whitehead, F. B. Wright.

M.B.,Ch.B.—Brenda M. Heathcote, W. B. Jennett, J. C. Richardson (with second-class honours); Margaret Addison, D. U. Bloor, Rosemary J. Bolam, R. Bradshaw, K. W. Brewster, P. Burrows, Anthea M. Bushby, Jean O. R. Carmichael, Mary I. Charlesworth, Jean M. Collins, Beryl C. Davies, Catherine M. Durkin, W. Ellis, O. L. Evans, Shelagh J. Fair, G. H. Fletcher, R. I. Green, I. W. Griffith, Margaret E. Hall, D. B. Hargreaves, J. F. Hobson, W. M. Hunter, P. Hurst, Margaret L. Johnson, J. L. Jones, R. E. Jones, R. H. Jones, Margaret Knox, Margaret A. Lees, Halina Z. Lewinska, D. H. Lloyd, Marcia McArthur, Audrey M. L. Owens, Ethel Owens, W. R. Parry, S. Plumpton, Sheila M. Pope, Ursula C. Pope, J. N. Rimmer, R. K. Rimmer, Myfanwy R. H. Roberts, E. Rogansky, H. U. Shaw, Pauline R. Sullivan, J. C. Taylor, R. P. Watkins, D. L. Williams, J. A. Williams.

D.P.H.—D. J. Cusiter, Elinor M. Evans, S. Ghousuddin, K. G. Koshi, D. A. W. Nugent, G. P. Reed, H. D. Sutherland, W. F. Wille.

Royal College of Surgeons of England

At a meeting of the council held on July 14 Sir Cecil Wakeley was elected president in succession to Lord Webb-Johnson. Sir Harry Platt and Prof. Ernest Finch were elected vice-presidents. Mr. Digby Chamberlain, Sir Stanford Cade, and Mr. A. Dickson Wright were admitted as members of the council. Prof. D. E. Derry, of Cairo, was admitted to the fellowship, having been elected as a medical practitioner of 20 years' standing.

The following were elected lecturers:

Hunterian professors: Mr. R. I. Harris, spondylolisthesis; Prof. C. F. M. Saint, stomatodæal ruminations; Dr. S. A. Henry, cutaneous cancer in relation to occupation; Mr. Denis Browne, congenital deformities of the urethra, vagina, and anus; Mr. J. B. Oldham, renal denervation; Mr. J. E. Piercy, safety in surgery of the thyroid; Mr. J. E. A. O'Connell, lumbar intervertebral disc protrusion; Prof. H. F. Moseley, ruptures of the rotator cuff; Mr. H. L. M. Roualle, malignant disease of thyroid gland; Mr. E. M. Evans, fractures of the radius and ulna; Dr. Ruth E. M. Bowden, functional recovery of peripheral nerve injuries; Mr. R. S. Murley, postoperative venous thrombosis and embolism; Mr. M. R. Ewing, villous tumours of the rectum; Mr. E. M. Nanson, respiratory responses to operative trauma. *Arris and Gale lecturers:* Mr. D. F. E. Nash, renal damage in chil Hirschsprung's disease; Mr. E. S. R. mammary gland. *Erasmus Wilson* Shattock, Mr. P. H. Mitchiner, Dr. L. *strators:* Mr. R. J. Last, Dr. F. S. Gorr Sir Henry Wade.

Diplomas of fellowship were granted to Manibhai Ashabhai Patel and Himadri Kumar Sarkar. The following diplomas were granted jointly with the Royal College of Physicians:

D.L.O.—B. S. Alderson, S. W. Allinson, Narendra Chandra Banerjee, H. A. Beagley, R. D. Bell, D. L. Chadwick, S. L. Citron, G. A. Dalton, W. V. Doyle-Kelly, C. N. d'E. Eastes, Ladislav Fisch, Tej Bahadur Gupta, E. W. R. Hackett, J. T. M. C. Jenkins, Thulukanam Manickam, Andrej Mares, S. R. Mawson, M. J. Maxwell, M. F. A. O'Connor, M. L. O'Mara, J. T. Rossouw, C. C. D. Shute, Noreen M. Simpson, J. N. S. Taylor, J. D. Thompson.

D.P.M.—Yousif Ibrahim Al-Kadi, G. H. L. Bullmore, R. L. Buttle, Tigani Elmahi, Markus Engler, M. B. Feldman, W. N. L. Haynes, Sri Kishen Jetley, D. H. Jones, D. T. Maclay, Jayantilal Chhotalal Marfatia, J. R. Mathers, Doddaballapur Lakshminarasimha Murti Rao, C. M. Vaillant, W. S. Watson.

Faculty of Anæsthetists.—T. J. Gilmartin, Alan Cogswell, T. T. P. Murphy, and W. D. Arnison were elected to the fellowship of the faculty.

Biochemical Society

A meeting of this society will be held in the biochemistry department, University College, Dundee, on Friday, July 29, at 11 A.M.

Edinburgh Post-Graduate Board for Medicine

On Thursday, July 28, at 4.30 P.M., in the anatomy lectur theatre of the university, Sir Lionel Whitby will speak o the Present Position Regarding Leukæmia.

Society of Medical Officers of Health

Dr. H. C. Maurice Williams, medical officer of health f Southampton, has been elected president of the society f the year 1949–50.

W.H.O. Executive Board

Sir Aly Tewfik Shousha, Pasha, has been succeeded in th chairmanship of this board by Sir Arcot Lakshmanaswam Mudaliar, vice-chancellor and professor of obstetrics an gynæcology in the University of Madras.

Institute for the Scientific Treatment of Delinquency

Courses of university extension lectures for the diploma i social studies will begin at the institute at the end o September. Further particulars may be had from th education secretary, 8, Bourdon Street, London, W.1.

Advisory Council for the Welfare of Handicappe Persons

The Minister of Health has appointed Mr. Edward Evan M.P., chairman of this council in place of Lord Rushcliff who has resigned owing to continued ill health.

Royal Institution

The managers of the institution have awarded the Actonia prize of 100 guineas for 1949 to Sir Alexander Fleming F.R.S., for his paper, published in 1945, on Penicillin—i Discovery, Development, and Uses in the Field of Medicin and Surgery.

Special Diets for Hospital Patients

The medical staffs of hospitals are reminded that they ma give certificates for extra rations to patients about to b discharged and to outpatients. The conditions for whic extra rations are granted and the medical information require are set out in the Ministry of Food Circular Med. 2, of whic doctors may obtain copies at the local food office.

British Medical Association

The council of the association is offering prizes in 195 to medical students for essays on Clinical Teaching in Relatio to the Practice of Medicine. Further particulars may be ha from the secretary of the association, B.M.A. House, Tavistoc Square, London, W.C.1, to whom essays should be sent no later than Dec. 31, 1949.

Conference on Health Education

The Central Council for Health Education is holding a national conference at the Central Hall, Westminster, S.W.1, on Tuesday and Wednesday, Nov. 8 and 9. Further information may be had from the medical adviser and secretary of the council, Tavistock House, Tavistock Square, London, W.C.1.

Congress of Military Medicine

The 12th Congrès International de Médecine et de Pharmacie Militaires will be held in Mexico from Oct. 23 to 29 and will be followed by a conference of the Office International de Documentation de Médecine Militaire at Havana from Nov. 6 to 8. The address of the Comité International de Médecine et de Pharmacie Militaires is 79, rue Saint-Laurent, Liége, Belgium.

Appointments

FERREIRA, H. P., M.B. Lond.: asst. pathologist to Queen Charlotte's and Chelsea Hospitals, at Chelsea Hospital for Women.

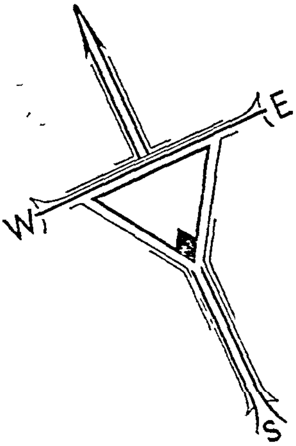
KEEPING, JOYCE, M.D. Lond., M.R.C.P.: physician, Paddingt Chest Clinic.

Hospital for Sick Children, Great Ormond Street, London:

HANNA, D. M., M.D. N.Z., M.R.C.P., M.R.A.C.P.: house-physician.
MACAULAY, J. C., M.B. Lond.: house-physician.
PIMM, L. H., M.B. Lond.: house-surgeon.
WALKER-BRASH, R. M. T., B.M. Oxfd: house-surgeon.
WATERSTON, D. J., M.B.E., M.B. Edin., F.R.C.S., F.R.C.S.E.: part-time surgical registrar.

for children everywhere

The problem of the run-down, debilitated child is shared by medical men throughout the world . . . and the universal answer is a tonic at once restorative, formative and protective. Syrup Minadex is such a tonic, combining three distinct therapeutic groups—iron, copper and manganese for their haemopoietic properties; the glycerophosphates of calcium, sodium and potassium, traditional nerve restoratives; and vitamins A and D to promote the growth of healthy tissues. These ingredients are combined in a delicious orange-flavoured syrup, making Minadex acceptable to the most fastidious palate in the warmest climate.



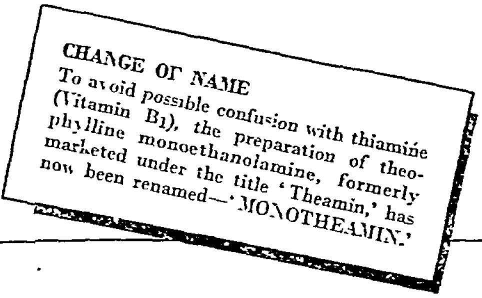
SYRUP MINADEX *the threefold tonic*

Research Laboratories Manufacturers of medical products and foods · Represented by associate companies or agents in almost every country of the world

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX, ENGLAND

'Monotheamin'

For Cardiac and Asthmatic Conditions



CHANGE OF NAME
To avoid possible confusion with thiamine (Vitamin B1), the preparation of theophylline monoethanolamine, formerly marketed under the title 'Theamin,' has now been renamed—'MONOTHEAMIN.'

'Monotheamin' brand theophylline monoethanolamine is a valuable therapeutic agent in the treatment of disease of the coronary arteries, whether the cardiac disability takes the form of congestive failure, paroxysmal dyspnœa or angina of effort. Administration is followed by an increase in both coronary flow and cardiac work.

The relaxing effect on the bronchial muscle, in minimal dosage, has proved of definite value in asthmatic conditions.

Supplied in 'Pulvules' brand filled capsules in three strengths —1 gr. (No. 283), 1½ grs. (No. 233), and 3 grs. (No. 225). Packed in bottles of 40, 100 and 500.

Descriptive literature will be sent on request.

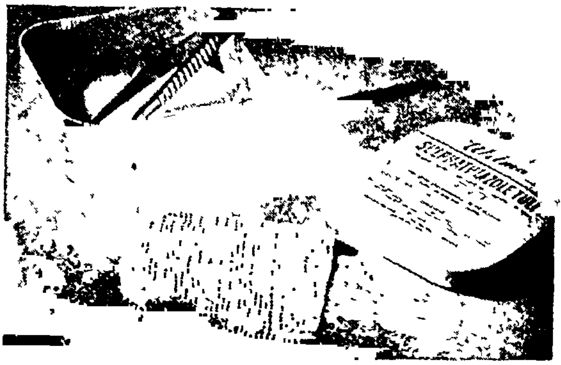
Lilly
TRADE MARK

The words 'Monotheamin' and 'Pulvules' are trade marks which identify products of Eli Lilly and Company.

ELI LILLY AND COMPANY LIMITED
BASINGSTOKE, HANTS

Wilmath REGD

SULPHATHIAZOLE TULLE



A wide mesh muslin impregnated with sulphathiazole, 5 per cent, in a paraffin jelly base. It is non-adherent and has been designed to prevent the carrying away of the sulphathiazole by the serum drainage. It is intended for the treatment of septic and potentially septic wounds, burns, ulcers and sloughs. Wilmath Sulphathiazole Tulle is packed in tins of 36 pieces, each 3½″ by 3½″. It is easy to apply. One piece is placed in direct contact with the wound and this is covered with an absorbent material such as cotton-wool. The wide mesh allows free drainage into the covering dressing.

"Mathaplast" REGD · SULPHATHIAZOLE ELASTIC STRIP DRESSING

Consists of surgical gauze impregnated in a solution containing 5 per cent sulphathiazole and stained with brilliant green. It is backed with adhesive plaister and is intended for use as a dry dressing. It is eminently suitable for small wounds. Striking evidence of its anti-bacterial action is afforded by the fact that when removed from a septic wound it comes away odourless. Apart from its sulphathiazole content, it is stained with brilliant green, an important therapeutic agent in itself. Obtainable in 1 yard lengths and in widths of 1½″, 2½″, and 3″.

ALOCOL

AL-O-COL

Colloidal Hydroxide of Aluminium

Rational Antacid Therapy

APART from those cases due to actual organic disease, the treatment of the syndrome of symptoms known as indigestion generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That "Alocol" possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Unlike sodium bicarbonate it does not give rise to secondary acid secretions nor to the discomfort of gas formation.

"Alocol" neutralises the excess acidity of the gastric contents to the most favourable degree for the promotion of healing of the damaged mucosa. It is prompt in the relief of pain and effects a soothing influence upon the gastric mucosa.

"Alocol" is free from the danger of alkalosis and excess dosage produces no ill effects.

"Alocol" is available in the form of Powder, Tablets or Cream

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request

ST. ANDREW'S HOSPITAL FOR NERVOUS AND MENTAL DISORDERS

NORTHAMPTON

PRESIDENT: THE MOST HON. THE MARQUESS OF EXETER, K.G., C.M.G., A.D.C.

MEDICAL SUPERINTENDENT: THOMAS TENNENT, M.D., F.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 130 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients, and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the complete investigation and treatment of Mental and Nervous Disorders by the most modern methods; insulin treatment is available for suitable cases. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultraviolet Apparatus, and a Department for Diathermy and High-frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research. Psychotherapeutic treatment is employed when indicated.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupational therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, [illegible] 'lst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the [illegible] may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bat[illegible] hore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and *facilities* are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (TELEPHONE: 2356 and 2357 Northampton), who can be seen in London by appointment.

THE RETREAT, YORK

The Pioneer Hospital, opened 1796, for the humane treatment of those suffering from Nervous and Mental Disorder

This Independent Hospital of 260 beds, administered by a Committee of the Society of Friends, combines what is best in the investigation and treatment of nervous illness with a sympathetic and friendly atmosphere. In 1948, 371 patients were admitted, of whom no fewer than 306 were voluntary cases.

Much curative work is accomplished in our mental hospitals today and the recovery rate compares very favourably with that of our general hospitals.

For information and terms of admission apply to:—

Extensively illustrated throughout text
The book has been completely revised to incorporate advances in surgery since the issue of the first edition. At the same time unnecessary matter has been avoided, so that the book remains a presentation of modern surgery of moderate size. The character of the book has been preserved but the additional matter makes it more generally useful to postgraduate as well as undergraduate students

THE GENTLE GIANT

'Albucid' Soluble in Ocular Therapeutics

FOR TISSUE of the highest sensitivity it is essential that local chemotherapy be effected by agents free from irritation. 'Albucid' Soluble Eye Drops are adjusted to pH 7.4 and are thus free from irritating alkalinity. High therapeutic efficiency, combined with ready solubility and very low toxicity, makes 'Albucid' Soluble the agent of choice in most eye infec 'Albucid' Soluble Eye Ointments, containing 'Alt Soluble in a neutral cream base, are available fc treatment of infections of the eye and lids, wh slower and more prolonged absorption may be sidered advantageous.

'ALBUCID' SOLUBLE

SULPHACETAMIDE SODIUM

EYE DROPS 10% and 30% in bottles of ½ oz.

EYE OINTMENT 2½%, 6% and 10% in tubes of 60 grains and 25 grams.

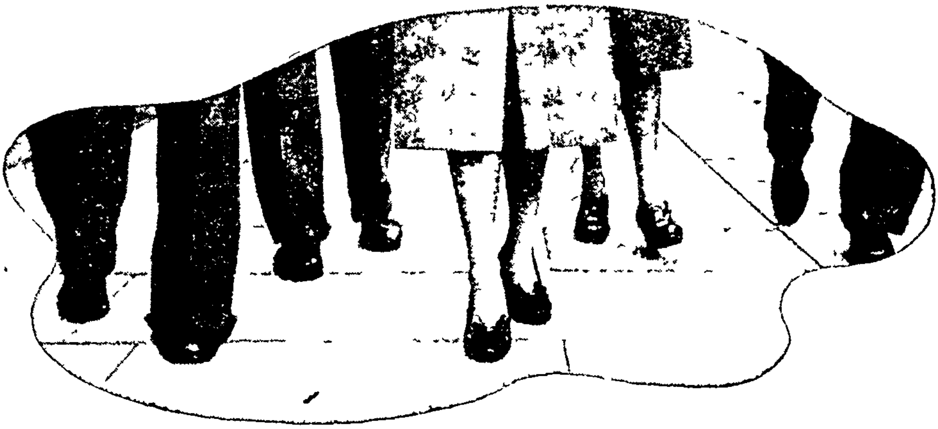
ENDOCRINE DISORDERS IN CHILDHOOD AND ADOLESCENCE

By H. S. LE MARQUAND, M.D. (Lond.), F.R.C.P. (Lond.), Physician, Royal Berkshire Hospital, and F. H. W. TOZER, M.D. (Lond.), M.R.C.P. (Lond.), Sometime Clinical Assistant, Royal Berkshire Hospital

HODDER & STOUGHTON LTD. 20, WARWICK SQUARE, LONDON, E.C.4



A Non-Mercurial Fungicide for Tinea Pedis

The summer season brings an increase in the number of cases of epidermophytoses of the feet (for example, athlete's foot) and similar fungal infections of the axillæ and perineal regions. Chlorphenesin (*p*-chlorophenyl-α-glycerol ether), evolved in the laboratories of The British Drug Houses Ltd., is a non-mercurial fungicide which is strongly inhibitive to the growth of the causative organisms of tinea pedis and most other epidermophytoses. Chlorphenesin is issued as 'MYCIL' Ointment and Dusting Powder. Clinical results confirm the effectiveness of the combined application. 'MYCIL' Dusting Powder is particularly useful as a preventive against re-infection when clinical cure has been obtained. Literature and samples will be forwarded on request.

MYCIL
TRADE MARK

Ointment in Containers of 1¼ oz.; Dusting Powder in Sprinkler Drums

Chlorphenesin is also recommended for the treatment of vaginal thrush
For this purpose it is issued as Mycil Pessaries in containers of 12

SURGERY FOR NURSES

By JAMES KEMBLE, Ch.M., F.R.C.S.

Supplies all that a Nurse should be expected to know of technical surgery, and has been based upon lectures given to Nurses over a period of years. Illustrations are numerous and too technical a presentation has been avoided.
Nurses in training will find this in every way an admirable book, while for those already qualified it will prove a help on many occasions.

Child Nutrition

It is now recognized that diet plays an important role in the health and development of children, and that good nutrition is particularly vital during the early years of life. Among the nutrients known to be essential for the maintenance of health are the vitamins of the B_2 complex.

One of the most useful, natural dietary sources of the B_2 vitamins is to be found in Marmite, which is a concentrated yeast extract. It has been shown that the systematic inclusion of Marmite in the diet is especially beneficial for expectant and nursing mothers, and for babies. Marmite is also ordered extensively for children of all ages.

MARMITE

MASS OBSERVATION–

SPECIAL REPORT

ON THE

HEALTH SERVICE

What do patients think of the National Health Service now that it has operated for a year? What are the chief complaints? Is the relationship between doctor and patient a good one? How many people still prefer a private system?

These are some of the questions put to a cross section of the Middle Class by Mass Observation, an independent team of specialists in social behaviour. The interesting, varied and often surprising conclusions, which every medical man should study most carefully, are published exclusively in

FOR THE BUSY PRACTITIONER

The convenience of tablet medication is undoubtedly of marked value in the treatment of many conditions presented daily to the physician.

This is particularly true of alkaline therapy, where ‘Milk of Magnesia’ Tablets are a frequent and everyday prescription. In the busy dispensary, or for providing immediate symptomatic relief while visiting the patient’s home, they present advantages readily appreciated by the practitioner.

Quickly dispensed, accurate in dosage and convenient to take during working hours, ‘Milk of Magnesia’ Tablets offer a simple yet efficacious means of combating gastric upset due to hyperchlorhydria.

SPECIAL PROFESSIONAL PACKS

For personal, surgery or dispensing use, a professional pack of ‘Milk of Magnesia’ Tablets is available. This contains 500 Tablets and costs 10/- (including tax) post free. Orders should be sent direct.

THE SPECIFIC AGENT AGAINST GRAM-NEGATIVE ORGANISMS

PHENOXETOL
REGD
NIPA

Phenoxetol is effective against Penicillin resistant organisms and compatible with Penicillin.

Phenoxetol is not inactivated in the presence of serum.

Phenoxetol is especially effective against gram-negative organisms including Ps. pyocyanea. It is used by local application in the treatment of infected wounds...abscesses ...indolent ulcers...associated with Ps. pyocyanea.

Phenoxetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparation of surfaces for skin grafting associated with Ps. pyocyanea, and may also be used together with Penicillin in solutions and creams.

Phenoxetol should not be used for parenteral injection.

OFF SCHEDULE...

Working at an accelerated pace, with their daily routine disrupted, more people than ever ignore the urge to evacuate, thereby increasing the incidence of constipation. Agarol* Emulsion provides deft and almost effortless supplementation to the finely balanced mechanism of normal evacuation. This smooth, palatable, free-flowing emulsion is geared to co-operate with natural physiological processes and to help to re-establish a regular schedule of bowel movements . . . by retaining moisture in the stool, by supplying lubrication and by mild stimulation of peristalsis.

AGAROL is supplied in 6 and 14-oz. bottles. It is available in 14-oz. bottles (minimum quantity six bottles in container) for dispensing only. Not subject to Purchase Tax when used on prescription.

GLANOID

LIVER AND YEAST CONCENTRATE

Combining Liver Extract, Yeast, Vitamins B_1 and B_2

Nutritional adequacy is a fundamental requisite for normal convalescence. "GLANOID" LIVER AND YEAST CONCENTRATE is an excellent nutritional adjuvant, not only because of the nutritional factors it contains, but also because of its tonic effect and stimulating action on the appetite. It hastens convalescence and helps overcome lassitude, fatigue and malaise. Furunculosis and inflammatory or ulcerative lesions of the mucous membrane may yield also to Liver and Yeast therapy.

"GLANOID" LIVER AND YEAST CONCENTRATE is absorbed rapidly and its physiological stimulating effect is noted promptly.

Packed in 4, 8, and 16 oz. bottles. Ample supplies available.

PENETRATING POWER

is more than half the battle

However potent an antifungal agent, it cannot be effective against tinea pedis or other dermatophytoses unless it readily penetrates the skin. 'Tineafax' Ointment contains undecylenic acid (recognised as a highly efficient fungicide) in a base of exceptional penetrative power. Clinical experience confirms that 'Tineafax' clears most cases of tinea pedis in from 7 to 21 days. It is bland, non-irritant, analgesic, clean and pleasant to use. 'Tineafax' Ointment is issued in collapsible tubes of 1 oz. (approx.); 'Tineafax' Powder, for prophylactic use, in 2 oz. sifter-top tins.

HE PREVENTION OF BURNS AND SCALDS

REVIEW OF 1000 CASES

LEONARD COLEBROOK
M.B. Lond., F.R.C.O.G., F.R.S.
TE DIRECTOR OF THE MEDICAL RESEARCH COUNCIL BURNS UNIT, BIRMINGHAM ACCIDENT HOSPITAL

VERA COLEBROOK

DURING the early years of this century both *The Lancet* .905, 1907) and the *British Medical Journal* (1910, 1912) epeatedly expressed concern over the deaths from burns nd scalds, which at that time totalled over 2000 a year, 0% of them in children. Coroners also spoke strongly n the subject, calling particular attention to the danger f leaving young children alone with an unguarded fire, nd to the extreme inflammability of the then comparaively new material flannelette, which had come into ommon use because it was comfortable to wear, easy to vash, and cheap (from 2¾*d.* a yard).

In 1908–09 the Government took two steps: Parlianent inserted clause 15 in the Children's and Young Persons' Act, 1908, which made parents liable to a fine of up to £10 if a child of 7 years or under was seriously injured or died from burns or scalds caused through an unguarded *open* fire (at that time electric and gas radiants were not in general use); and the Home Office appointed a committee to report on the dangers of flannelette and on a method of fireproofing it with stannic oxide which had recently been patented by Prof. W. H. Perkin, of Manchester, in association with a firm of flannelette manufacturers.

TABLE I—COMPARISON OF HOME AND INDUSTRIAL BURNS AND SCALDS ADMITTED TO THE MEDICAL RESEARCH COUNCIL BURNS UNIT, BIRMINGHAM ACCIDENT HOSPITAL, 1945–48

Burns and scalds	Age-group (years)					Deaths	Case-mortality (%)	Stay in hospital (days)
	4 or less	5–14	15–64	65 or more	Total			
At home ..	373	117	166	43	699	44	6·3	24,402 (av. 34·9)
In industry	0	6	292	3	301	4	1·3	10,180 (av. 33·8)
Total ..	373	123	458	46	1000	48	4·8	34,582 (av. 34·5)

Neither of these steps was effective. Magistrates were reluctant to add to the burden of parents whose child had died; and in any case prosecutions were rare. Of twelve prosecutions reported in the *Times* in 1909 under the new Act only one was for neglect to provide a fireguard. In practice, therefore, clause 15 was a dead letter from the start, and today many parents do not even know it is still law. The flannelette inquiry was also abortive, but for reasons difficult to understand (see below).

The war of 1914–18, which broke out soon after the committee's report was issued, brought much graver dangers to the nation, and the deaths of children from burning were forgotten. Since then, the number of deaths, particularly from burns, has steadily declined; but the annual total in England and Wales is still about 1000. Several factors have probably contributed to the falling death-rate: the replacement of naked gas flames and paraffin lamps by electric lighting in the homes; smaller families and the consequent reduction in overcrowding; the better care of burned people which began in 1925 with the introduction of tannic acid; the declining virulence of the hæmolytic streptococcus (which was the chief cause of fatal sepsis); and the much greater control over these infections in recent years with the sulphonamides (1936) and penicillin (1942).

But, though the death-rate has fallen, it should not be assumed that the number of accidents has decreased in proportion. Unfortunately there are no data on this point. What is certain is that the accident-rate is still high—a conservative estimate puts it at 100,000 burns and scalds needing hospital treatment every year in England and Wales alone—and that these accidents, even if not so fatal as formerly, are a very serious liability to the person concerned and to the community. As *The Lancet* (1946) put it in a leading article:

> "Few calamities leave deeper scars on mind and body . . . the sum of misery to the victims and their relations is still enormous."

In a word, we have little reason to congratulate ourselves on our efforts to prevent these accidents. The open fire grate is still in every home, usually unguarded and without staples at either side of the fire to which a guard could be fixed; highly inflammable fabrics are still almost universally used for children's wear; and, whereas in the early part of this century the mother could buy a fireproofed flannelette if she could afford it, now she cannot buy it at all (see below). Moreover, new perils have come into the home, particularly the unguarded mobile electric fire and the panel gas or electric fire placed in the wall, unguarded, at precisely the height of a child's frock; and little or nothing has been done either to warn or to protect the public.

All these considerations compel us to ask: "What new approach to the problem is required, and, in the first place, what data are available to guide us?"

Some of these data have already been set out by one of us (Colebrook 1946). The report was based on the Registrar-General's returns and the early experience (1945–46) of the Medical Research Council burns unit at the Birmingham Accident Hospital. We have since carried the investigation further, analysing the first 1000 patients admitted to this burns unit from 1945 to August, 1948, including the 253 briefly considered previously by Colebrook (1946).

It has sometimes been suggested that Birmingham is exceptional in having so many of these accidents. That is not so. With the help of the Registrar-General's office and the Ministry of Health we have ascertained the death-rate per million per year (from burns and scalds) for each of the 83 county boroughs of England and Wales during 1945–47. Of the 12 boroughs with a population exceeding a quarter of a million 9 have had a higher death-rate than Birmingham —some of them more than twice as high. And of all the 83 boroughs only 19 have had a lower death-rate than Birmingham. The reason why many cities do not realise the magnitude of their burns problem has been discussed by Colebrook (1949).

Analysis of 1000 Case-records

These 1000 cases represent little more than half the burns and scalds requiring inpatient treatment in the Birmingham area. During 1945–47,* while 736 (53%) of

Case-mortality (%)	*2 6*	*2·5*	*4·8*	*53·5*	*6·3*

Deaths, included in totals, are shown in parentheses.

E

A new treatment for **insect bites** *and* **stings**

The present tendency to ascribe the painful effects of insect bites and stings to the action of histamine has suggested the use of antihistamine therapy in alleviating the symptoms. Encouraging results have been obtained with 'Anthisan' administered orally. Rapid reduction of the wheal formation and relief of painful symptoms have been experienced in the majority of cases. Failure to respond to 'Anthisan' is an indication for the substitution of the more powerful antihistaminic, 'Phenergan'. Some measure of relief can be secured by the local application of 'Anthisan' Cream.

'ANTHISAN' *trade mark brand*

mepyramine maleate

Oral : 0.05 Gm. & 0.10 Gm. tablets
in containers of 25, 100 & 500

Topical : Containers of 1 oz. and 1 lb.
2 *per cent.* cream

'PHENERGAN' *trade mark brand*

promethazine hydrochloride

Oral : Containers of 100 and
500 x 0.025 Gm. tablets

HE PREVENTION OF BURNS AND SCALDS

REVIEW OF 1000 CASES

LEONARD COLEBROOK
M.B. Lond., F.R.C.O.G., F.R.S.
TE DIRECTOR OF THE MEDICAL RESEARCH COUNCIL BURNS UNIT, BIRMINGHAM ACCIDENT HOSPITAL

VERA COLEBROOK

DURING the early years of this century both *The Lancet* 905, 1907) and the *British Medical Journal* (1910, 1912) peatedly expressed concern over the deaths from burns nd scalds, which at that time totalled over 2000 a year, 0% of them in children. Coroners also spoke strongly n the subject, calling particular attention to the danger f leaving young children alone with an unguarded fire, nd to the extreme inflammability of the then comparaively new material flannelette, which had come into ommon use because it was comfortable to wear, easy to ash, and cheap (from 2¾*d*. a yard).

In 1908–09 the Government took two steps: Parlianent inserted clause 15 in the Children's and Young ersons' Act, 1908, which made parents liable to a fine of up to £10 if a child of 7 years or under was seriously injured or died from burns or scalds caused through an unguarded *open* fire (at that time electric and gas radiants were not in general use); and the Home Office appointed a committee to report on the dangers of flannelette and on a method of fireproofing it with stannic oxide which had recently been patented by Prof. W. H. Perkin, of Manchester, in association with a firm of flannelette manufacturers.

TABLE I—COMPARISON OF HOME AND INDUSTRIAL BURNS AND SCALDS ADMITTED TO THE MEDICAL RESEARCH COUNCIL BURNS UNIT, BIRMINGHAM ACCIDENT HOSPITAL, 1945–48

Burns and scalds	Age-group (years)					Deaths	Case-mortality (%)	Stay in hospital (days)
	4 or less	5–14	15–64	65 or more	Total			
At home ..	373	117	166	43	699	44	6·3	24,402 (av. 34·9)
In industry	0	6	292	3	301	4	1·3	10,180 (av. 33·8)
Total ..	373	123	458	46	1000	48	4·8	34,582 (av. 34·5)

Neither of these steps was effective. Magistrates were reluctant to add to the burden of parents whose child had died; and in any case prosecutions were rare. Of twelve prosecutions reported in the *Times* in 1909 under the new Act only one was for neglect to provide a fireguard. In practice, therefore, clause 15 was a dead letter from the start, and today many parents do not even know it is still law. The flannelette inquiry was also abortive, but for reasons difficult to understand (see below).

The war of 1914–18, which broke out soon after the committee's report was issued, brought much graver dangers to the nation, and the deaths of children from burning were forgotten. Since then, the number of deaths, particularly from burns, has steadily declined; but the annual total in England and Wales is still about 1000. Several factors have probably contributed to the falling death-rate: the replacement of naked gas flames and paraffin lamps by electric lighting in the homes; smaller families and the consequent reduction in overcrowding; the better care of burned people which began in 1925 with the introduction of tannic acid; the declining virulence of the hæmolytic streptococcus (which was the chief cause of fatal sepsis); and the much greater control over these infections in recent years with the sulphonamides (1936) and penicillin (1942).

But, though the death-rate has fallen, it should not be assumed that the number of accidents has decreased in proportion. Unfortunately there are no data on this point. What is certain is that the accident-rate is still high—a conservative estimate puts it at 100,000 burns and scalds needing hospital treatment every year in England and Wales alone—and that these accidents, even if not so fatal as formerly, are a very serious liability to the person concerned and to the community. As *The Lancet* (1946) put it in a leading article:

> "Few calamities leave deeper scars on mind and body . . . the sum of misery to the victims and their relations is still enormous."

In a word, we have little reason to congratulate ourselves on our efforts to prevent these accidents. The open fire grate is still in every home, usually unguarded and without staples at either side of the fire to which a guard could be fixed; highly inflammable fabrics are still almost universally used for children's wear; and, whereas in the early part of this century the mother could buy a fireproofed flannelette if she could afford it, now she cannot buy it at all (see below). Moreover, new perils have come into the home, particularly the unguarded mobile electric fire and the panel gas or electric fire placed in the wall, unguarded, at precisely the height of a child's frock; and little or nothing has been done either to warn or to protect the public.

All these considerations compel us to ask: "What new approach to the problem is required, and, in the first place, what data are available to guide us?"

Some of these data have already been set out by one of us (Colebrook 1946). The report was based on the Registrar-General's returns and the early experience (1945–46) of the Medical Research Council burns unit at the Birmingham Accident Hospital. We have since carried the investigation further, analysing the first 1000 patients admitted to this burns unit from 1945 to August, 1948, including the 253 briefly considered previously by Colebrook (1946).

It has sometimes been suggested that Birmingham is exceptional in having so many of these accidents. That is not so. With the help of the Registrar-General's office and the Ministry of Health we have ascertained the death-rate per million per year (from burns and scalds) for each of the 83 county boroughs of England and Wales during 1945–47. Of the 12 boroughs with a population exceeding a quarter of a million 9 have had a higher death-rate than Birmingham —some of them more than twice as high. And of all the 83 boroughs only 19 have had a lower death-rate than Birmingham. The reason why many cities do not realise the magnitude of their burns problem has been discussed by Colebrook (1949).

Analysis of 1000 Case-records

These 1000 cases represent little more than half the burns and scalds requiring inpatient treatment in the Birmingham area. During 1945–47,* while 736 (53%) of

TABLE II—DISTRIBUTION OF HOME BURNS AND SCALDS IN AGE-GROUPS, SHOWING CASE-MORTALITY RATES

Deaths, included in totals, are shown in parentheses.

---

* The figures for the other five hospitals during 1948 are incomplete.

these injuries were admitted to the Accident Hospital, a further 624 (45%) were admitted to the other five large general hospitals—Dudley Road Municipal Hospital, Selly Oak Municipal Hospital, Children's Hospital, General Hospital, and Queen Elizabeth Hospital—and it may be assumed that a few more, probably not less than 30 (2%), were admitted to other hospitals in the area. In the period under review about 3000 further patients received outpatient treatment at the Accident Hospital for burns or scalds.

PLACE OF ACCIDENT, AGE, AND SEX

The number of burns and scalds resulting from accidents in or around the home was 699 (70%), compared with 301 (30%) industrial accidents; and the case-mortality rate was also much higher in the group of home accidents: 6·3% compared with 1·3% (see table I). Birmingham is a city of very varied industries, many of which involve the use of molten metals and a consequent heavy risk of burns to the workers. Probably in many less industrialised communities the preponderance of home burns and scalds would be even greater.

Injury from burns and scalds fell far more heavily on children than on any other class. Table II shows that of the 699 accidents in or around the home 373 (53%) happened to children under the age of 5 years, and 490 (70%) to children under 15 years. When these totals, and those for adults, are related to the estimated mean population for the same age-groups (taking the national figures for 1935–39 as about correct), the incidence of burns and scalds per 10,000 of the population of Birmingham is as follows:

For children aged under 5 years	49·5
„ „ „ 5 to 14 „	7·5
„ adults „ 15–64 „	5·0
„ „ „ 65 or more years	4·8

TABLE III—DISTRIBUTION OF HOME BURNS IN RELATION TO NATURE OF ACCIDENT

Deaths, included in totals, are shown in parentheses.

Scalds were rather more common than burns among the very young children, but they produced less severe injuries and were rarely fatal. The case-mortality rate for burns in children under the age of 5 years was 5·5%, but for scalds only 0·87%. The proportion of boys to girls scalded was 3 to 2.

Among patients aged 65 years or more, burns were three times as common as scalds; the proportion of women to men was 5 to 1. The case-mortality rate for burns among these older people was 68·7% (74% for wom and 40% for men; see table II).

BURNING ACCIDENTS IN THE HOME

Of the 213 burning accidents to children under th age of 15 no less than 114 (53%) resulted from dire or indirect contact with heating appliances, such a open coal fires and gas and electric radiants (table III Of these 114 accidents 104 (91·2%) occurred when guard was on the fire; in a further 3 cases the being unfixed, was removed by the child. In a fur 7 cases the children's clothing was ignited when lighted gas oven was left open to warm the room. In 3 of these cases the children were still in their night cloth (all of flannelette or winceyette) at about 10.30 A.M.

Of the 32 burning accidents to people aged 65 or more at least 20 (62·5%) occurred when no guard was on th fire; and it is significant that in 9 of the 20 accidents this group of which we have full information an unguarded gas or electric radiant was responsible for the injury. Children and old people appear to stand in particular danger from these types of heating appliance (table III).

The design of the clothing of elderly women, as well as (sometimes) its inflammability, together with the greater preoccupation with cooking, tending the fire &c., were presumably responsible for the much high incidence of burns sustained in this age-group compared with men of the same age (22 to 3; see table III).

Among the burning accidents which were *not* due t contact with a heating appliance the most importan groups were those attributable to the improper use o inflammable liquids, usually petrol or paraffin, and thos caused by fires outside the home—ashpits, bonfires fireworks, &c. (table III). Only 2 patients came to th hospital from a house on fire, and both recovered. A first we thought that many more might have received fatal burns in conflagrations and were not brought to th hospital, but inquiry showed this not to be so. It may be noted also that in the Registrar-General's Returns 1900–39 the deaths due to conflagrations amount to only 3% of the total—2682 out of 78,911.

Of the 360 home burns admitted, 134 (37%) resulted from the clothes catching fire; and usually † the gar

---

† Unfortunately the records did not always include a precis statement on this point, but our impression is that the garments burned were of flannelette or winceyette in at least three-quarters of the cases. Complete records are now being kept.

TABLE IV—PROPORTION AND DISTRIBUTION OF CASES IN WHICH CLOTHES CAUGHT FIRE

Deaths, included in totals, are shown in parentheses.

se 3 accidents happened as follows:
A spark from a fire set alight a child's clothing.
A child removed the guard standing before an electric fire.
A child's clothes and perambulator cover were ignited by clothes airing at the fire.

se included: inflammable liquids 11, fires outside the house 9, lighted gas oven used to warm room 8, matches 7, lit paper, &c., 4, igarette 4, candle 2, log taken out of gas oven ignited cotton apron 1, gas stove 1, and cause unknown 3.

ignited were of cotton material, such as flannelette, ette, print, &c. (table IV).

le IV shows that all age-groups contain many females than males burned by contact of their ig with an unguarded fire. In those aged 65 or he ratio was 16 to 1. The 81 victims of the acci- associated with an unguarded fire had a decidedly death-rate than those whose clothes were ignited ier means. The average stay in hospital was also —and it has to be remembered that in most of fatal cases (included in the total of 81) the victims ithin a few days of the accident; otherwise the ge stay in hospital of this group would have been still.

SCALDING ACCIDENTS IN THE HOME

339 scalding accidents in the home by far the number—228 (67%)—involved children under e of 5 years; and of these 228 scalds in children curred when the child pulled or knocked over a or cup of tea or a container of other scalding put down within its reach. A further 35 accidents ldren under the age of 5 years were caused by buckets, wash-tubs, &c., left on the floor (see v).

PART PLAYED BY EPILEPSY

epsy was an important ancillary factor in the tion of home burns. Of the 209 adults burned or d 35 were epileptics, the accidents happening during In all these 35 cases the diagnosis of epilepsy was d by the history. Several other patients whose nt coincided with a "fainting fit" or a "turn" ho had not a clear history pointing to epilepsy iot included. In 29 of the 35 burning accidents ing epileptics no fire-guard was in use at the time.

ASSESSMENT OF PREVENTABILITY

en reasonable care and foresight on the part of lult concerned, whether victim or guardian (see table VI), 55% of the home burns and 44·5% of the home scalds are judged to have been preventable. It is fully realised that any assessment of preventability is beset with difficulties. Too little allowance may have been made for the peculiar circumstances in which the responsible adult was placed at the time of the accident; and, on the other hand, fuller acquaintance with those circumstances might sometimes show the seemingly "pure-chance" accident to have been easily preventable. Broadly speaking, we have regarded the burning accidents associated with the unguarded fires as preventable (except when the guard had been temporarily removed for making up the fire), because these accidents were almost always due to momentary contact with the source of heat, a contact which could not have happened if a guard had been in place. It is noteworthy that 62·5% of the burns of old people were of this kind. By contrast, the setting alight of a child's frock by a spark shot out from a coal fire was regarded as "not easily preventable"; and so was the burn due to the splashing of hot fat. But the pulling over of a container of hot fat, put within the reach of a young child, has been taken as "preventable."

The scalds of young children were judged to be preventable if a teapot or cup of hot liquid was knocked or pulled over by the child (because it could usually have been put out of the child's reach), but it was judged "not easily preventable" if the accident was due to a mother slipping—or to a child running into her—while she was carrying a saucepan or kettle. Again, the accident was usually judged "preventable" if a young child fell into a bath or bucket of hot water left on the floor while the mother went to fetch the soap, &c.; but "not easily preventable" if an older child or adult tripped or fell into hot water.

We have included 36·4% of all the burns and scalds in the "not easily preventable" class. The "unclassifiable" group (13·6%) was composed of the accidents of which the particulars obtained were insufficient to allow of any opinion.

TABLE V—DISTRIBUTION OF HOME SCALDS IN RELATION TO NATURE OF ACCIDENT

Nature of accident	Age-group (years)					Case-mortality (%)	Stay in hospital (days)
	4 or less	5–14	15–64	65 or more	All ages

ers of other scalding liquids pulled or ked over by patient	62	17	..	..	79	..	2763 (av. 34·9)
&c., left on floor	35(2)	7	..	..	42(2)	4·8	1171 (av. 28)
auses	51	15	51	11(1)	128(1)	0·7	3969 (av. 31)
Total	228(2)	49	51	11(1)	339(3)	0·8	10,544 (av. 31)

Deaths, included in totals, are shown in parentheses.

TABLE VI—ASSESSMENT OF PREVENTABILITY OF HOME BURNS AND SCALDS

Assessment	Burns		Scalds		Total	
	No.	% of total cases	No.	% of total cases	No.	% of total cases
Preventable ..	198* (8409)	55·0	151† (4895)	44·5	349 (13,304)	49·9
Not easily preventable	124 (4155)	34·4	131 (4090)	38·6	255 (8245)	36·4
Unclassifiable..	38 (1294)	10·6	57 (1559)	16·8	95 (2853)	13·6
Total ..	360 (13,858)		339 (10,544)		699 (24,402)	

Days of occupation of hospital beds are shown in parentheses.

* Of these 198 burns (representing 6905 days in hospital), 152 were associated with unguarded fires.

† Of these 151 scalds, 116 (representing 1706 days in hospital) resulted from the upsetting of tea or other hot fluids (all the patients were children) and 34 from the leaving of baths, &c., on the floor.

EXPENDITURE OF HOSPITAL SERVICES

In spite of the exceptionally favourable facilities for the treatment of burns and scalds at the Birmingham Accident Hospital the 1000 cases under investigation involved the occupation of hospital beds for no less than 34,582 days (24,402 for home accidents and 10,180 for industrial).

Table IV shows that the burns due to contact of clothes with unguarded fires involved the longest stay in hospital (59 days average) and the highest case-mortality rate. As was remarked above, the average stay in hospital would have been considerably longer if the patients who died—usually within a few days—had survived.

It is noteworthy too that the group of scalds among children under the age of 5 years accounts for a large proportion of the occupancy of hospital beds.

It is seen too that, if the home burns and scalds judged to have been preventable had been prevented, this occupancy of beds would have been reduced by no less than 13,304 days (349 cases). In terms of the whole country such a reduction would amount to something like 300,000 bed-days, possibly more. And these figures take no account of the casualty and outpatient services rendered to a very large number of patients.

Prevention

Very briefly, the data summarised above point to the following four chief conclusions:

(1) There are considerable risks from fire and hot water—many of them avoidable risks—in the modern English home.

(2) These risks are greatest for young children before they have developed "heat sense."

(3) Special risks are associated with the clothing of girls and women.

(4) Burns and scalds—apart from their cost to the persons concerned—make heavy demands on hospital services.

Attempts to reduce the number of these accidents in the past have too often been along a single track—e.g., by focusing on the neglect of fire-guards or on the dangers of flannelette. We believe that the attack should be from several different directions simultaneously, recognising that many factors contribute to each mishap. All of the following may be expected to have some effect—some more, some less. Together they might well reduce the number of these accidents within a few years to half the present figure.

(1) *Education and propaganda* by film, radio, the press, exhibitions, posters, demonstrations and talks in women's institutes, community centres, schools, &c., and, perhaps most important of all, by the continued personal effort of doctors, welfare workers, district nurses and visitors, and the staffs of postnatal and health centres.

(2) *Better houses and living conditions:* the elimin overcrowding. Too often the children can only play the fire in the living-room.

(3) *The freeing of women from industry* to look a homes and children.

(4) *Safer methods of heating houses:* by contra perhaps, district heating and by the wider use of coal fires (of the 'Aga' type) and convector types of fires.

(5) *The wider use of uninflammable materials* clothing of girls and women.

(6) *Better design of guards for coal fires* and facili fixing them in place, so that children cannot remove

(7) *Better design of gas and electric fires* adequately

(8) *Better design of teapots and cups and of cooking* rendering them less easy to upset.

In planning this preventive campaign it wil helpful first to consider some of its more impo elements separately.

CIRCUMSTANCES LEADING TO SCALDS

Scalding accidents, to which very young childre particularly liable, are too often due to a lack of aw ness of the danger on the part of the mother. She not learnt to be on her guard instinctively, as she down the cup or pot of tea, lest the baby's arm sh fly up and knock it over, and to place it on the habitually well out of the baby's reach. She has realised—or she forgets—that the toddler playing o floor is very likely to grab hold of the corner of the t cloth, bringing the teapot crashing down over him and that the slightly older inquisitive boy is likel catch hold of the handle of the saucepan and upse

These accidents and many others of a similar kind w be less frequent if the tea-cups and teapots had broad base rather than the incurved one; and si improvement in design of other cooking utensils w make for safety.

But a wisely directed and persistent campaig education and propaganda will probably be most effe in preventing this kind of mishap.

BURNS ASSOCIATED WITH HEATING APPLIANCES

Open Coal Fire

This is still the outstanding hazard of the En home. The experience of Birmingham suggests that responsible for nearly 300 deaths and 2000 non- injuries, severe enough to require admission to hospi in England and Wales alone each year. In the distant future this hazard is likely to grow less import In spite of the Englishman's traditional attachment his open fire the paramount need for economising and saving labour will probably lead to consider development of central and district heating. Ele and gas fires and cookers have already taken the p of coal in many homes and are likely to continue t so in many more.

It is difficult to see how the open coal fire can be made safe. Much might have been done—and m still be done—by the better design of fire-guards; the fire-guard will always have to be removed for sto the fire and for cooking; and it will always be diff to prevent the adventurous child from removing it w the mother is out of the room (unless the fire-gua padlocked). The provision of staples in the wall on e side of the grate to which the fire-guard can be atta is long overdue. We understand that at present in m council houses a tenant, even with young childre not allowed to put such staples in without see permission; and often to put them in is not a si matter after the fireplace has been built. We sugges local authorities that such staples should be include routine in all new houses to begin with, later to be ad in all existing council houses.

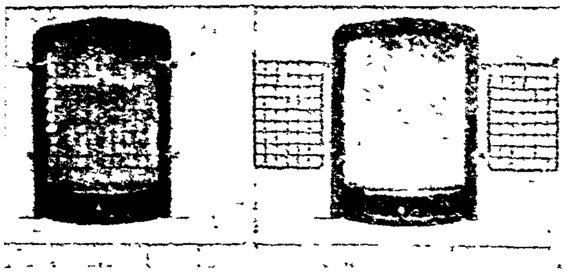

Fig. 1—Hinged fire-guard for open fire.

Ve also suggest for consideration the merits of a guard rporated in the open fire grate, either in the form of nged gate, as shown in fig. 1 (an experimental model le for us by Mr. Hartley, a builder, of Wexham. ugh), or in the form of a built-in guard of which the els can be pulled out from the walls when required. uard of the second type has been designed by Mr. W. J. rthington, a Birmingham architect, and is being rketed by Messrs. Metalcraft, also of Birmingham.

ELECTRIC AND GAS RADIANTS

The importance of these fires (especially the electric) a source of burns has steadily increased during the t fifteen years. Though electric fires were in short ply during the recent war, great numbers of them ne on to the market and were widely bought during hard winter and the coal crisis of 1947. Most of the ctric fires are mobile and of light construction; hence y can easily be knocked over. The heat in the immedi- vicinity of the naked element is usually much greater n that of the yellow flame of a coal fire; hence contact ting only 1–2 sec. with an inflammable material is ficient to set it burning fiercely. Though many are ed with one or more bars to safeguard the element, y few carry a guard designed to prevent a frock or ht-dress *from touching the element*—an omission ich has undoubtedly led to hundreds of deaths. At a ent visit to the Ideal Home Exhibition in London we nted 28 of these inadequately guarded, and therefore safe, fires to 8 safe types.

We call particular attention to the great danger of the nel type of electric and gas fire flush with the wall standing a few inches away from it and usually at t the height of a child's frock. In our own limited perience very terrible burns have already been caused these fires, which could so easily be made safe by the dition of a small guard at the time of manufacture. is should be made compulsory.

There are no data about the total number of accidents roughout the country caused by electric and gas fires recent years, but our experience in Birmingham ring 1945–48 leads us to the conclusion that the figure England and Wales in each of these years is likely have been at least 1400, with nearly 250 deaths. The e figures may well have been considerably higher.

When these facts have been presented to the manu- cturers of these fires (as they have been on several casions during the past three years), we have usually en met with the contention that any guard would tract from the appearance and efficiency of these aters, and therefore from sales. Tests of efficiency ve shown conclusively that a light guard at a few ches from the element makes very little difference to e radiation effect. And a well-designed guard need not tract from the appearance. In the matter of sales lue, possibly if the public were plainly told of the nger of these unguarded fires the provision of safe- ards would quickly come to be a selling feature. It ight even earn dollars. And, if the manufacturers will not show themselves sufficiently concerned about the public safety, the sale of these fires should be subject to specific safety regulations analogous to those which protect the public against the indiscriminate sale of dangerous drugs and poisons.

Gas "Pistol"

With many of the newer gas cookers a "pistol" lighter can be purchased. This "pistol" tucks loosely into a loop of metal at the side of the cooker, and is within the reach of a child. A child can easily depress the small knob which releases a long jet of flame from the barrel. There is real danger that a child may at some time blind a playmate. We suggest that this "pistol" should never be installed at oven height but should always be hung well above the cooker; as a further safeguard, the loop could be made to fit more tightly, making it difficult if not impossible, for a small boy to detach the "pistol."

HEATING APPLIANCES BURNING PARAFFIN OR OTHER LIQUID FUELS

Improved designs of these fires are coming on the market and will present their particular problem. Their manufacture and sale should also be subject to appropriate safety regulations.

INFLAMMABLE CLOTHING MATERIALS

"Clothing caught fire" was the story behind most of the serious injuries. In our series it was responsible for 36 of the 41 deaths due to burns in the home: and the average stay in hospital for those who survived was 72 days as compared with 34·8 for all burns and scalds. The striking difference between the sexes, as regards number of cases and of deaths (tables III and IV), clearly suggests that the clothing of the female children and older women (in association with unguarded fires) exposes them to a much greater risk than does that of males. And that suggestion is strongly confirmed when we consider the inflammability of the clothing materials in common use, and the design of female clothing.

To anyone who has exposed a piece of woollen material and a piece of flannelette to a match or candle flame or to the element of an electric heater there is no need to labour this question of *inflammability*. The woollen material smoulders with a red glow, withdraws from the source of heat, and goes out. The flannelette burns like a torch, and the material is usually completely destroyed within a few seconds. But so many people of all classes seem to be unaware of this great difference that we add the results of a few tests made with various clothing materials.

Following the procedure of *The Lancet* (1911) laboratory we have applied a small flame, not to the cut edge of the material under test (which tends to exaggerate its inflammability), but to a point about 1 in. above the edge. Since we had to work with a vertical flame (of a night-light), the material in our test was conveniently held, at an angle of about 40° from the horizontal, on a piece of wire netting. Under these conditions ignition of the material was a little less rapid and complete than it would have been in the vertical position.

The point of the small flame (about 13 × 3 mm.) was brought up to the material for 6 sec. and then promptly removed; 15 sec. later the burning (if any) was quenched by applying sheets of felt firmly above and below the wire netting. (The 6 sec. exposure to the flame was a little longer than was necessary. With 3 sec. exposure ignition of the material was uncertain; with 4 sec. it started, sometimes a little sluggishly.)

The materials tested were all of recent manufacture except the silk. They were acquired in the retail market. Most of them had not been washed. Their dryness was ensured by exposing them for several hours before testing 2–3 ft. from a coal fire. Samples tested were 3 in. square.

The results were as follows:

Test no.	*Material*	*Result*
1	Standard flannelette *	Visible flame 3–4 sec. from start, which spread rapidly, destroying 75% of the material within 15 sec.
2	Flannelette from retail market, good quality	As above
3	Winceyette retail market, poor quality	As test 1, 70% destroyed
4	Winceyette (white) retail market, better quality	As test 1, 75% destroyed
5	Winceyette (another sample, coloured)	Ignition slightly slower, 40% destroyed
6	Ditto	As test 5, 45% destroyed
7	'Dayella' (mixture of cotton and wool) retail market	As test 1, burning not quite so fierce, 60% destroyed†
8	Ditto (repeated)	As test 1, flamed fiercely; 90% destroyed
9	'Viyella' (mixture of cotton and wool)	*As test 1, 50% destroyed*†
10	Rayon	Ignited but did not burn quite so fiercely as the previous tests, 50% destroyed
11	Woollen fabric (knitted)	This was held vertically and flame held to cut edge for 15 sec., no ignition, and no destruction of material
12	Black silk (pre-war quality)	Test as no. 11, did not flame, a red glow developed at one point but went out immediately flame was removed, destruction almost nil
13	'Nylon' (two samples)‡	Melted round the source of heat but there was no flame and no spreading destruction

* Made to Specification No. 3012 issued by the Cotton Board on behalf of the Board of Trade 1942.

† When tested with an electric fire these two materials ignited suddenly at 3–4 sec. with a slight explosion.

‡ A third sample, sold as nylon, burned freely, but was found on microscopical examination to be a mixture of nylon and cotton.

It is clear from tests 1–6 that all the samples of raised cotton materials were highly inflammable; and it may legitimately be inferred that any garment made of these materials which remained in contact with a naked flame *or with the element of an electric or gas fire for 4–6 sec.* would have burned equally readily, particularly if it stood away from the wearer's body, and if the wearer was upright and created currents of air by moving. The chances of escaping a severe burn when so clad must be slight.

By contrast with these results with cotton fabrics, it proved almost impossible to set alight wool and silk fabrics with the small flame used in these tests. These materials may be regarded as virtually uninflammable, though the woollen material tested could be made to burn fiercely by contact with an electric fire for 30 sec.

It was somewhat surprising and disappointing to find that the fabrics containing a mixture of wool and cotton, which are much used at present by all classes of the community, were almost as inflammable as the raised cotton materials, though slightly less ready to catch alight at first. Interlock, a knitted cotton material, which has the advantage that garments made from it do not stand away from the body, was in the same category. Rayon too was moderately inflammable.

Two of the three fabrics sold as nylon differed from all the others in that they melted but did not burn.

We were unable to compare the inflammability of these modern materials with that of the fabrics available in 1910, and probably more refined methods of testing would have been necessary to determine any small differences. Judging from the published accounts of tests carried out by the British Fire Prevention Committee in its Red Book No. 148 and by *The Lancet* (1911) laboratory, the results obtained were very similar; and the safety coefficient of the materials in common use has not appreciably improved.

THE HOME OFFICE INQUIRY OF 1908–10

The cotton fabrics with the raised nap have come into such general use by all classes of the community (especially those in the poorer homes, where the fire hazard is greatest) during the past sixty years ‡ that it is imp to discuss the problem of clothes catching fire wi special reference to these materials. Nor can one these materials without special reference to the Office inquiry of 1908–10, because the results of inquiry have *a direct bearing on the incidence of* today.

The proceedings of this committee and its fin are not readily accessible today because they are of print, and are available in very few libraries. B they deal with many questions which will certainly to be discussed afresh, we discuss them here in detail. (The evidence will be found in the *Second R of the Departmental Committee on the Law relating Coroners, 1910*; and the final report in vol. XX *Reports of Commissioners, Inspectors and others* publ by the Stationery Office in 1910.)

The committee was primarily concerned with different matter—i.e., the law relating to coroners—in view of the great increase of children's deaths burning since the introduction of flannelette (an incre apparently of 62% for children under the age of 5 yea *it was asked to consider whether any action sho* be taken and, in particular, about the merits certain uninflammable materials which were attract attention.

From the evidence submitted the committee a with the view expressed by many coroners and surg that the high inflammability of flannelette was a ma contributory factor in many burning accidents, but also emphasised the important parts played by absence of fire-guards, carelessness with regard to matc candles, &c., and frequent failure to keep a proper w over young children in the home. It decided that th were no reliable data about the proportion of burn accidents for which flannelette was chiefly to blame. did not favour a system of compulsory marking flannelette which would warn the public of the dan arising from its inflammability.

It considered at some length the merits of a process fireproofing flannelette by impregnation with sta oxide, which had been introduced and patented Prof. W. H. Perkin, F.R.S., in 1902. Material so proo had been on the market for a few years under the n 'Non-Flam,' and several million yards of it had produced at the time of the inquiry. The uninfla bility of this material (which is well illustrated in was amply established by the evidence of Sir T Thorpe, director of the Government laboratory, a independent investigations carried out by the Fire Prevention Committee and published i Red Book No. 148; and by another committee, co of Prof. Sims Woodhead, Sir William Ramsay, P Pope, Dr. Kelynack, and Mr. J. C. Cain, of the Che Society.

Sir Thomas Thorpe's evidence showed that its u flammability was slightly reduced by the first was but scarcely at all by *subsequent washings. It was* established that the fireproofing process gave the mat any properties which rendered it unsuitable for ma into garments. In the committee's summing up not is said about any such disadvantages but, for s reason which is not clear to the reader today, it st that the non-flam process did not appear to be *f* satisfactory (italics by the committee).

In forming this conclusion the committee was ap ently influenced by two considerations: (1) that proofed material had not already established itself public favour as an alternative to the *ordinary flannele*

---

‡ Since about 1945 the pure cotton materials have been in s supply for the home market and their price has grea increased. In consequence the demand for mixed cotton wool fabrics, and pure wool, has increased, but, as shown abo the safety coefficient of the mixed materials is not great improved.

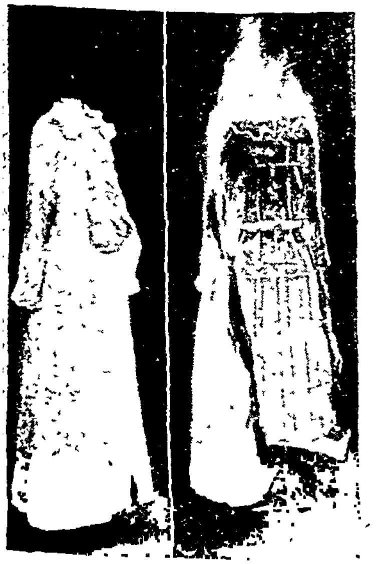
(2) that its price was higher than that of the roofed flannelette and therefore it had not been, would not be, bought by a large part of the popula-. As regards (1) the evidence given to the committee ws that there was strong opposition within the cotton le to the introduction of non-flam (which was tected by patent rights). Professor Woodhead ribed to the committee the reluctance of retailers to him non-flam though they had it in stock. If this ctance was general, and was possibly prompted by manufacturers of the unproofed fabrics, it would go to explain the fact that non-flam had not won popular our. And no doubt the price charged to the public l also played a part. It was not clear from the evidence mitted how much more the retail buyer was asked to for the proofed material compared with the same terial unproofed (there were several grades of proofed flannelette on the market, ranging from l. to 8¾d. a yard). It may well be that exorbitant ces were sometimes asked for non-flam. The cost of oofing was apparently from ¾d. to 1d. a yard, but tnesses explained that some additional charges would ve to be made for advertising and selling it.

It seems probable that, if the committee had represented to the Government that the wide use of proofed brics was essential for the saving of child life, and that ofessor Perkin's process provided such a satisfactory oofed material, the difficulty of price could have been ercome by negotiation with the manufacturers; and at, if due publicity had been given to the advantages using the safe material, it would quickly have come to popular favour—at least with a large part of the ople.

If that had happened, it is likely that the lives of some ousands of children would have been saved in these tervening forty years, and many more spared the rrible results of non-fatal injuries.

As it was, the committee contented itself with the commendation that the public should be protected ainst the sale of fabrics which were alleged to be eproof but were not—at any rate after being washed. ffect was given to this recommendation after three years by the Fabrics (Misdescription) Act, 1913. In concluding its report the committee said:

> "Legislation of the kind suggested is the less justifiable in view of the fact that matters may, in course of time, be expected to right themselves. Great improvements have already been made in the manufacture of flannelette, and further improvement may be anticipated. New and cheaper methods of diminishing the inflammability of the material may be discovered."



g. 2—Tests of inflammability: (a) flannelette fireproofed with stannic oxide, at 120 sec; (b) ordinary flannelette, at 60 sec. A lighted taper or spirit-lamp was applied to bottom edge of garment for not less than 15 sec. or more than 20 sec. Similar results to those in (a) were obtained with non-flam after it had been washed and *dried twenty times*.

Today, forty years later, matters have not righted themselves. In spite of anticipated improvements in the manufacture of flannelette it remains highly inflammable—indeed we know of no evidence that this danger has been reduced at all. Some new methods of fireproofing have been discovered, but, so far as we are aware, none has yet proved better than the stannic-oxide process. Actually progress has been backward. Forty years ago a mother could at least buy an uninflammable cotton garment if she was prepared to pay a little more for it; today she cannot.

Looking back on the work of this committee it is difficult to resist the conclusion that it was singularly ineffectual. If there were reasons why non-flam should not be widely used by the public for clothing, the committee entirely omitted to present those reasons. If, on the other hand, that material provided the way to safer clothing for millions of women and children, the committee, by omitting to represent that to the Government, lost a great opportunity of saving life and of preventing an incalculable amount of suffering.

It is not easy to discover what was the subsequent history of non-flam. In 1912 it was awarded the £50 prize offered by the *Daily Express* for the safest cotton material. And in 1913 the patents covering its production were revoked by consent so that after that time it could have been taken up by other manufacturers. Was it killed by the Home Office committee's omission to represent that it was at least an important step in the right direction, or by the opposition of the cotton trade, which was evidently much concerned at that time about the effects of the inflammability scare on the sales of flannelette? (It should be noted that the name "winceyette" has gradually taken the place of "flannelette," but, as we have shown, the difference in inflammability is practically nil.) Or was the process dropped during the war of 1914–18 because of the shortage of tin? or did it fail to survive because the nation was too preoccupied with the tragedy of the war to bother much about lesser things? Whatever was the fate of non-flam, there can be no doubt that the possibility of proofing flannelette and kindred wearing materials should be reconsidered without delay in the light of present knowledge.

Recent investigations at the Royal Aircraft Establishment on similar problems in relation to fire hazards in the Services have yielded some data on the various processes by which fireproofing can be effected. Using 'Aero Cotton' (a fabric of different texture from flannelette but of similar weight) as their test material, Ramsbottom (1947) found that impregnation with stannic oxide had two disadvantages: it caused serious deterioration of the fabric after protracted exposure to sun and air; and the inflammability of the proofed material was regained after boiling for 30 minutes. Whether flannelette is affected in the same way as aero cotton we do not know—no such changes were reported to the Home Office Committee—but clearly such effects must be looked for in any new investigation.

Fresh light has also been thrown by the R.A.E. investigation upon the mechanism by which some of the older methods of fireproofing achieved their results. It may well be that this in turn will point the way to quite different and more successful processes.

Whatever process is ultimately adopted it is likely to add something to the cost of production of the materials; but it is probable that, if the dangers of ordinary flannelette and the merits of a proofed material were made known to the public by a Government sincerely concerned to prevent these burning accidents, the great majority of mothers would gladly pay the extra few pence in the interest of safety.

In this matter of cost it may be well to remind ourselves of the price we have paid in the last forty years since the fireproofing of flannelette became (apparently) a practical *proposition.* There are *no reliable data*—and probably not all would agree about the apportionment of the blame in some cases—but our own continual contact with burning accidents through several years leads us to the conclusion that not less than 100 children in England and Wales each year owe their deaths primarily to the fact that the garment they were wearing could *easily* catch alight by touching a fire. If that is true it means that in these forty years we have lost at least 4000 children (and the correct figure would probably be higher). For each one who has died there have been at least five times as many who have suffered the terrible experience of large septic, slowly healing, burns, and have ultimately recovered with greater or less permanent disability. There must have been at least 20,000 of these unfortunate children. Is this *to go on for another forty years* before we take steps to see that children are clothed in safer materials?

SUMMARY

Analysis of 1000 consecutive admissions to the Medical Research Council burns unit, Birmingham Accident Hospital, of patients with burns and scalds has shown that 70% of the patients had been injured by an accident in or around the home, and only 30% at the place of work; 70% of the home accidents happened to children, those under the age of 5 years being most affected.

About half of all the home accidents were judged to have been preventable—i.e., they would not have happened, given reasonable care and foresight on the part of the adult concerned.

The expenditure of hospital services on these accidents was very heavy. The 1000 cases, in spite of exceptionally favourable circumstances for their treatment, occupied beds for no less than 34,582 days. If the home accidents judged to have been preventable had been prevented, this occupancy of beds would have been reduced by 13,304 days.

It is estimated that in England and Wales alone each year injuries of this kind must require at least 1,000,000 hospital bed-days.

The association in the home of a naked source of heat and highly inflammable garments worn by women and female children and the younger boys is still the ultimate cause of the most serious accidents, *as it was in 1908* when the Home Office Committee inquired into the matter.

An examination of the proceedings and report of that committee leaves a strong impression that a great opportunity was lost at that time to substitute for the almost universally used inflammable flannelettes similar materials rendered uninflammable. This possibility should be reconsidered without delay.

At the same time other preventive measures should be pursued. These should include:

(1) improvement in the design of guards for open fires, and proper provision made for fixing them in all new houses being built by local authorities; (2) regulations requiring that all electric and gas fires offered for sale must conform to certain definite safety standards, which would include adequate guarding; and (3) nation-wide propaganda maintained for several years by radio, the press, the cinema, demonstrations, exhibitions, talks in schools and community centres, &c., and by personal contact.

HOUSE-SURGEON

KING EDWARD VII HOSPITAL, WINDSOR

INFECTIONS of the hand are today recognised important surgical condition, and during the last there have been considerable changes in the treatment. With the formation of hand clinics better understanding of the surgical principles the results have improved considerably.

Iselin[1] describes the serious results that at one followed infections of the hand; long periods of stiff hands and fingers, infected bone and joints, even fatal results were all too common. These complications are rarely seen today, but there remains room for improvement, particularly in the taken to obtain healing and full function. A few are *still seen in which serious complications* arise—infections of bone, joint, and tendon—usually in p who came late to hospital for treatment.

Three measures have to a large extent contribute the improved results seen today: (1) immobilisatio the infected hand and abandonment of foments, soaks, dry heat, and frequent dressings, &c.; (2) therapy has probably reduced the incidence of complications; and (3) the method of excision of slough and suture after incision has led to an even period of disability.

We describe here the results obtained by using all measures described above, particularly in cases by excision and suture as described by Loudon et a[2] 100 cases treated in the first six months of 194 which the notes were adequate have been analysed.

ÆTIOLOGY

In the 100 cases analysed there was a history of in 34 and a foreign body was found at operation cases.

The age of the patients ranged from 1 to 67 62 were males and 38 females; 60% were workers, 22% worked at home or were children, and 17 were office workers.

The average length of history was 7·4 days, but cases which subsequently healed without full it was 9·5 days. If such cases could be seen earlier

* One case developed both bone necrosis and an adherent slough.

tle doubt that the results would be further ved.

commonest digit to be infected was the left thumb, the right thumb a close second, whereas the left finger was infected least often. The type and ency of infections seen are shown in table I, together he results of treatment. Two patients had a double ion, so 102 fingers were involved.

TREATMENT AND RESULTS

nservative treatment by immobilisation and chemopy alone was attempted in 3 cases of pulp infection; case the infection was aborted, but in the other 2 cal treatment became necessary. Preoperative peni- 250,000 units was given in all cases. Pus may be ous when the case is first seen; otherwise its presence be indicated by pain and local tenderness. In cases oubt the hand was treated by conservative means there was more definite evidence.

99 cases an incision was made, and pus was obtained l. After cleaning out the pus and excising any slough nt, it was possible to suture 55 cases. All cases were ated on with a rubber band at the base of the finger, pneumatic cuff on the arm, to ensure a bloodless . It was not always possible to use a standard sion, since the pus had sometimes ruptured through skin; the incision was then made in the position of sinus. If the skin was intact, lateral incisions in the ger were used and, if necessary, turned into flaps to ure adequate excision of the slough. In the hand, nsverse or L-shaped incisions were used.

TABLE II—RESULTS OF EXCISION AND SUTURE

Site of infection	No. of cases	No. sutured	Primary healing	Unsatisfactory
nychiæ	29	2	2	Nil
al pulp	46	35	31	1 stitches cut out; 2 pus reformed; 1 pain caused stitches to be removed

EXCISION-SUTURE TECHNIQUE

A tourniquet and general or local anæsthesia were d so that at least 15 minutes could be spent on the ration. The operation was done under proper theatre ditions. The most suitable incision was made, the scess cavity was opened, the pus was mopped out, a careful search was made for any sloughs. If sent they were excised completely. This is an essential p in this method. The incision was then closed if ssible with interrupted stitches of black silk. It important not to tie these stitches too tightly, for tissues may swell and cause the stitches to cut t.

If there is skin necrosis, or if there is doubt about the nplete excision of the slough, the incision should not sutured. If the skin edges are only slightly necrosed, margins can be brought together with a few stitches ing a wider bite through the healthy skin.

The main advantages of this method are early healing th complete comfort for the patient.

No serious complications followed this method, but it led in 6 cases out of 55 (table II). These unsatisfactory results were mainly due to failure to excise the whole slough. This method involves more operating time, but there is a big saving in nursing time, since the dressings are left untouched for a week. Symptoms may necessitate earlier removal of the dressing, but this occurred on only 2 occasions in the present series.

TABLE III—COMPARISON OF SERIES WITH AND WITHOUT EXCISION AND SUTURE

Site or type of infection	1948		1947	
	No. of cases	Length of disability (days)	No. of cases	Length of disability (days)

Web	3	15	3	40
Mid-palmar	2	18	—	—
Thenar space	—	—	2	20
Total infections and average length of disability	102	14 6	101	28·1

PARONYCHIÆ

The excision-suture method is not often applicable in these cases; it was used twice, when a nail flap was turned down. All these cases were treated by removal of part of the nail or, occasionally, the whole nail.

Pulp Infection (Finger)

It is in these cases that the excision-suture method can be used most often with the greatest advantage. Necrosis of the skin was the main factor in preventing suture, and it was also considered unwise to suture if there was definite bone necrosis, as shown by preoperative radiography.

Middle and Proximal Pulp Infections (Finger)

These cases were treated on the same lines as pulp infections, but excision of sloughs was not so often necessary.

Dorsal Infection (Finger)

Out of the 5 cases seen, 4 were treated by the excision-suture method; each case healed by first intention.

Flexor Tendon-sheath Infection

These cases should be admitted to hospital. Only 1 case occurred in this series; it was treated by exposing the proximal and distal ends of the sheath by a small transverse incision through the skin and sheath. The pus was milked out, and 5 ml. of penicillin (5000 units per ml.) was instilled along the length of the sheath. Both wounds were sutured, and they healed by first intention in seven days. Full function was present in twenty-six days.

Web Infections

These were treated by the usual web incision, cleaning out the pus, and suturing the skin; they all healed by first intention.

Mid-palmar Space Infections

In 1 case skin necrosis prevented suture; in the other one the skin was sutured but gaped in part, and some delay occurred in healing.

Anæsthesia

In 27 cases a digital block was produced with 2% procaine with 2% adrenaline (1 : 1000). In small doses the addition of adrenaline is safe and enhances the anæsthesia. General anæsthesia was used in the other cases.

Postoperative Treatment

No form of external drainage was used, and the wound was dressed with sulphathiazole-penicillin powder (5000 units per g.) with tulle gras. In all cases the affected part was immobilised by a dorsal plaster slab and elevated in a sling.

Most patients were given aqueous penicillin 250,000 units b.d. for three days by intramuscular injection. A week later the wound was dressed for the first time, and, if all evidence of infection had subsided, the patient was told to use his hand or finger. If there was much limitation of movement, he was referred to the physiotherapy department for exercises. This treatment must not be started until all infection has subsided. 33 cases were referred for exercises, and only 1 case had slight residual stiffness of the fingers when the patient was last seen.

Results

Most patients were operated on by one of us (H. D. W. P.), but some were treated by the house-surgeon on duty; therefore exact uniformity of technique was not always possible. It has been impossible to analyse 100 consecutive cases, because some patients did not attend for follow-up, and in other cases the records were incomplete. We feel that the length of disability is the best criterion by which to judge the results in infections of the hand. By this we mean length of time taken for the wound to heal and full movement to be present. Healing time may be misleading, as full function is not necessarily present.

Our results are shown in table III, where they are compared with a similar series of cases treated a year earlier. In the earlier series the excision-suture technique was not used, external drainage was common, and daily dressings were applied in most cases.

It will be seen that the average length of disability has been halved since excision and suture immobilisation have been used. The improvement is most striking in pulp infections. We have followed the technique described by Loudon et al.[2] fairly closely. The incisions have been rather smaller than those advised, and we have not often used flaps. Admittedly the slough was incompletely removed in some cases, but we feel that this was due to failure to excise the slough fully and not to inadequate exposure.

The complications seen were bone necrosis and adherent sloughs; both these results could be largely avoided if the cases were seen earlier. In 1 case excision of a large slough left a depressed scar when the finger healed; 2 cases required reincision later owing to pus re-forming.

What of the future? How can these hand infections be further reduced in number and severity? Further propaganda is required in factory, office, and home about the proper care of all cuts, &c. If penicillin could be given within a few hours of the onset of the symptoms, and the affected part immobilised, many infections might be aborted.

SUMMARY AND CONCLUSIONS

The excision-suture technique is another valuable step forward in the treatment of hand infections. It reduces the disability period and ensures greater comfort for the patient; it can be used with advantage in any busy casualty department once the principles are fully understood. The method was followed in 55 out of 100 cases analysed here.

We agree that immobilisation is of prime importance.

Chemotherapy is of considerable value in preventing and controlling serious complications; its value in well-localised infection of the hand is less certain.

In our view there is no place for rubber drains, hot foments, soaks, dry heat, &c., in the treatment of hand infections.

SOME RECENT APPLICATIONS OF

A. Hirsch
B.Sc., Ph.D. Reading

A. T. R. Mattic
B.Sc., Ph.D. Lond.

From the National Institute for Research in Dairy
University of Reading

Nisin, the antibiotic produced by *Strep. lactis,* to be of practical value. It is mainly effective gram-positive organisms, including the tubercle Its value resides in its bactericidal nature, and injections are remarkably effective against streptococcal and clostridial infections in the (Mattick and Hirsch 1947). It also appears to be ef in experimental tuberculosis. Recently this was used in a field trial against bovine strepto and staphylococcal mastitis (Taylor et al. 1949). only single infusions of nisin in oil (1 ml.) were the percentage cured was very high.

Nisin has the properties of a polypeptide or of low molecular weight. It is soluble in dilute and the solution is heat stable. It tends to pr tate at neutrality and is slowly labile under all conditions.

METHODS

In the experiments described below the prep of nisin crystals were made by Berridge (1949) concentrates supplied by Benger's Ltd. Solutio N/50 HCl were used for in-vitro tests. For inje these solutions were brought to pH 4, with formation of a haze.

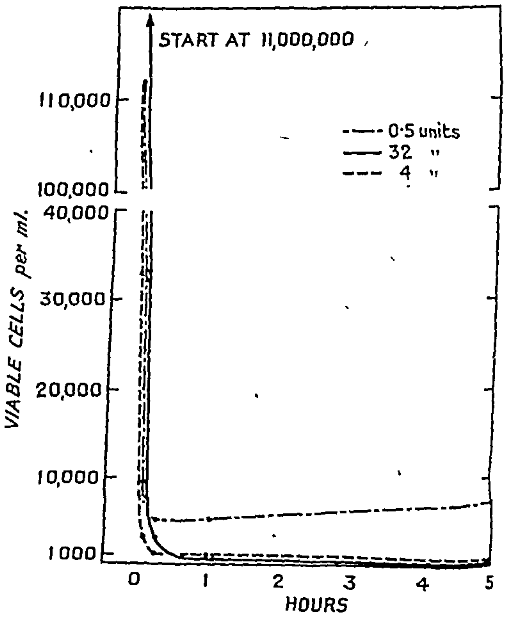

Fig. 1—Effect of nisin on viable count of *Strep. agalactiæ.*

The first blood-nisin levels were estimated modifications of Fleming's (1944) capillary assay, reproducible results were not obtained by this met The "lag-phase" assay which overcame these difficu was finally adopted (Hirsch 1949). The assays made on the serum, which appears to contain all activity.

BACTERICIDAL POWER OF NISIN

The bactericidal power of nisin was tested *in vi* small quantities of nisin being added to a heavy cul of *Strep. agalactiæ.* A typical result with count illustrated in fig. 1. An experiment to explore behaviour in vivo was made. Mice infected with *St* *pyogenes* "Richards" were given a single subcutane injection of 20,000 units after the establishment infection. Mice were sacrificed at interv the heart, and counts were made on blood-agar. urve, almost identical with fig. 1 was obtained. figure shows that nisin is rapidly bactericidal, a reduction in the count being obtained in the first inutes. Other antibiotics, such as penicillin, which appear to be bactericidal, require several hours' tact to achieve a comparable reduction in numbers.

TOXICITY

he subcutaneous LD50 of crude nisin was reported Mattick and Hirsch (1947) to be about 3·5 g. per kg. similar systematic investigation has yet been made determine the LD50 of the purified material, but an roximate idea of the toxicity was gained from imations of blood-nisin levels in about 30 rabbits.

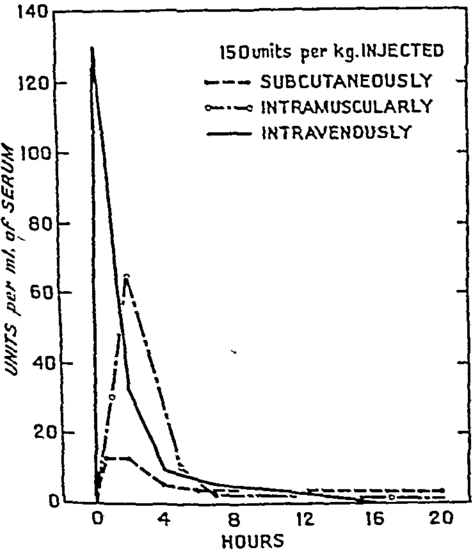

Fig. 2—Blood-concentrations of nisin after single injections.

The results show that the toxicity of "pure" nisin pends on the route of administration. Intravenously rabbits, 5,000,000 units (33 mg. per kg.) was always al whereas 3,000,000 units (20 mg. per kg.) was not, ough often the rabbit showed signs of distress and e blood did not clot normally. The LD50 intravenously thus between 20 and 33 mg. per kg. Similarly the 50 intramuscularly is about 200 mg. per kg., and bcutaneously it is greater than 1000 mg. per kg.

Rabbits which receive a fatal intravenous dose of sin die quietly and within a few minutes. Similar jection in guineapigs leads to violent spasms, the mptoms of both these conditions resembling "peptone ock" as described by Wilson and Miles (1946).

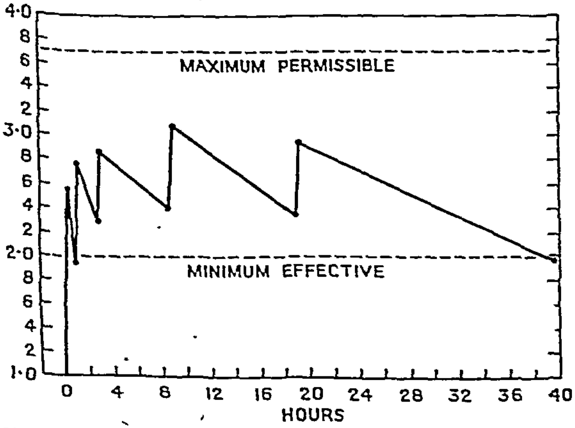

Fig. 3—Blood-concentrations of nisin after repeated injections at 0, 1, 3, 8, and 19 hours.

TABLE I—EFFECT OF NISIN ON ERYTHROCYTES

„ 0·2 „ „ „ ..	–	–	+	–	–	–
Control; no acid	–	–	+	–	–	–

After necropsy the kidney, liver, spleen, heart, and lungs of these rabbits were suspended, according to their moist weight, in compensated volumes of *N*/20 HCl, and the tissues were put through a Folley and Watson (1948) blender and placed in a boiling water-bath for 5 minutes to extract the nisin. After centrifuging the samples were assayed. A similar procedure was carried out with the lesions at the site of repeated subcutaneous injections (see below).

All the internal organs contained some nisin, but by far the highest concentration was in the lungs. The subcutaneous lesions contained almost all the nisin which was injected, a finding which probably explains the low toxicity of nisin given by this route. In fact, owing to non-absorption the subcutaneous route is unpromising.

The "peptone shock" symptoms of fatal doses of nisin are not usually reproduced when the injection is given slowly (1 ml. per minute) with a perfuser. Slowly injected nisin kills at the same level as rapidly injected nisin, but death seems to be due to respiratory failure. No gross systemic effects have been noted.

EFFECT OF NISIN ON BLOOD

The effect of crude nisin on leucocytes, as estimated by the technique of Abraham et al. (1941), has already been reported by Mattick and Hirsch (1947). Though there was no apparent action, this observation remains to be confirmed with the purer preparations. The effect of purified nisin on red blood-cells was tested by the technique of Rammelkamp and Weinstein (1941), and the results given in table I show nisin to be non-hæmolytic in the highest concentrations tested and which could be expected in vivo.

Berridge (1949) reports that nisin is soluble in ox blood to the extent of at least 5000 units per ml., and E. M. Bavin (private communication) puts this figure at 20,000 units for mouse blood. In any case, judging by the in-vitro sensitivity of the more resistant mycobacteria, even the lower figure is sufficient to secure effective therapy.

BLOOD LEVELS

The blood levels obtained after single injections of nisin are given in fig. 2, which shows that the behaviour is according to anticipation: low concentrations for longer times were obtained by the subcutaneous route than by the intravenous route, which gives high peaks

TABLE III—EFFECT OF NISIN IN EXPERIMENTAL TUBERCULOSIS

Exp. no.	Nisin used	Animals used	No. of animals	Infecting strain	Route of infection	Treatment, hours after infection	Route of treatment	Dosage		Duration		Toxicity		Results

of short duration. The intramuscular route occupies an intermediate position.

Fig. 3 illustrates an experiment in rabbits, which was the culmination of preceding experiments designed to stabilise the blood levels between two arbitrary levels of "maximal permitted" concentration (5000 units per ml. of serum based on the solubility figure of Berridge) and "minimal effective" dose (against mycobacteria) of 100 units per ml. of serum. The results show that the excretion (or inactivation) of nisin is gradually slowed down after repeated injections, and that, after an initial "saturation," satisfactory blood-nisin levels could be obtained by 12-hourly injections.

Blood levels of 1–10 units per ml. of rabbit serum are obtained by feeding nisin in the mash.

EFFECT OF NISIN ON MYCOBACTERIA

In Vitro

The sensitivity in vitro of various strains of mycobacteria to nisin was first tested in Long's synthetic medium, and the inhibiting dilution was judged to be that concentration of nisin which prevented the development of pellicles. These results are shown in table II. It will be seen that 100–300 units of nisin were required for complete inhibition; but, when later these experiments were repeated in the medium of Dubos and Davis (1946) containing 'Tween 80', only 1–3 units were required for inhibition, an effect noted with other antibiotics (Dubos 1948). In this medium nisin appears to have about the same activity, weight for weight, against the mycobacteria as streptomycin (Smith and Waksman 1947, Crofton and Mitchison 1948).

Working with *Myco. phlei* and strain H37RV of *Myco. tuberculosis* in the medium of Dubos and Davis, we tested combinations of nisin with other drugs fairly extensively for synergic and other actions. It is almost impossible to construct a single table to show the various levels at which each of the antibiotics is effective, since large variations were encountered from experiment to experiment. Each experiment, however, contained adequate controls—i.e., the antibiotics considered were always assayed alone as well as in combinations in every experiment—and thus it is possible to conclude that there was no synergism, or even marked additive action, between nisin and streptomycin or between nisin and licheniformin. Combinations of three antibiotics—e.g., nisin, streptomycin, and licheniformin—led, however, to increased activity, which could not be ascribed to a combination of any of the two. A similar behaviour is shown by nisin, licheniformin, and sulphathiazole, though more than a mere additive action appears exist with combinations of nisin and sulphathiaz If, by serial subculture in increasing concentrations each of the three antibiotics used, resistant cultures each one were prepared, these were still suscepti to the action of the other two antibiotics. Sulp thiazole-resistant cultures were also still sensitive nisin.

It can therefore be seen that streptomycin- cultures are sensitive to nisin, and vice versa– important finding, since there seems to be little do that there is some correlation between the strepto resistance of the infecting strain of the tubercle baci and the prognosis of the illness (Medical Research C 1948).

In Vivo

The effect of nisin in vivo on the tubercle was tested in four experiments, details of which given in table III. So far only prophylactic experime have been made, and much still remains to be learn The data given in table III illustrate this point. In first experiment crude nisin was used, and this reduc the spread of infection. It was hoped that purifi nisin, which was used in a similar way in the second a third experiments, would be of more value. Despite t very much purer nisin which was used, the outcome these two experiments was similar to that of the firs The results can largely be attributed to the fact th nisin forms insoluble subcutaneous pockets from wh there is but little absorption. This explains the loc reaction, as shown in table III.

Experiment no. 4 was undertaken when it was realis that nisin was bactericidal and that a high blood-ni level could be obtained by the intravenous route. Th was some hardening of the veins at the site of injecti but otherwise no reaction to nisin was observed. T result of this experiment, though made on very f animals, is rather striking. Thus, at the time necropsy, the controls had generalised tuberculos but macroscopically infection could not be detected the treated group. Histological examination, howev revealed early tuberculosis.

SUMMARY

Nisin is bactericidal in vitro and in vivo. It see to have no effect on blood, but its toxicity depends the route of injection. Severe local reaction on repeat subcutaneous injections is obtained. Intravenously a intramuscularly there is rapid absorption with little ocal reaction, and the approximate LD50 is 30 mg. kg. with intravenous injection and 200 mg. per kg. ι intramuscular injection.

he H37RV strains of *Myco. tuberculosis* which are :tant to nisin are susceptible to streptomycin and versa. More than additive effect against H37RV btained where nisin is used with streptomycin and eniformin, or with licheniformin and sulphathiazole. iven subcutaneously nisin limited the spread of erimental tuberculosis. Given intravenously it almost pletely suppressed its development.

'e wish to thank Mr. N. J. Berridge, PH.D., and Messrs. ger's Ltd. for gifts of nisin used in this work.

NTRAMEDULLARY ABSCESS OF THE SPINAL CORD

JOHN FOLEY
M.A., M.B. Camb., M.R.C.P.
ISTANT IN THE NEUROSURGICAL UNIT, ATKINSON MORLEY HOSPITAL, LONDON

)F the suppurative conditions related to the spinal d, extradural abscess is the commonest; it may ow trauma or local disease of bone, or may arise as netastatic infection from some distant source, often oil. Its early recognition is important because ener- ic treatment, by means of antibiotics and laminec- ny, may be successful if undertaken before the aplegia becomes complete.

An abscess formed within the dura but outside the d itself is rare. It is usually the result of localisation a purulent meningitis, or of trauma.

ntramedullary abscess of the spinal cord is extremely e. In the past it has proved almost uniformly fatal, t by modern methods the suppurative process may localised and the abscess successfully drained.

PREVIOUS REPORTS

Arzt (1944) reviewed 37 cases of intramedullary cess reported since 1830, and added 3 fatal cases ociated with infective endocarditis. Since then Ameli 48) has reported 1 case with recovery, and Vlasova 45) mentions 4 fatal cases following spinal wounds.

The ages of the patients (Arzt, Ameli) ranged from ht days to seventy-five years; 25 were males, 15 re females, and in 1 the sex was not mentioned. Of 9 cases below the age of fifteen, 7 were girls, but after lescence males predominated.

No level of the cord is exempt, though there appears to a predilection for the lower dorsal and lumbar seg- nts. In 12 of 42 cases the abscess extended over more n five segments: in one it had extended from the dulla to the lumbar region before death occurred. In laminectomy was performed: 6 of these patients d, 1 was left with an unimproved paraplegia, and mproved enough to walk. Of the 18 cases occurring fore 1900 all were fatal except 1, in which a paraplegia remained despite exploratory operation. Laminectomy with recovery has been reported by Woltman and Adson (1926), Walker and Dyke (1936), Alessi and Fasiani (1940) and Ameli (1948).

Origin

The cause was most often a blood-borne infection from a distant septic focus (26 of 42 cases); less commonly the infection spread into the cord from suppuration in neighbouring tissues (9 cases), and in 7 cases no source could be found. Where infection was deemed to be blood-borne, chronic suppurative pulmonary disease was the commonest cause, with infective endocarditis coming second (and usually causing multiple miliary abscesses); less frequently pelvic disease (including septic abortion, urethritis, vaginitis, and prostatic abscess) was responsible; 3 cases were due to actinomycosis, 2 to otitis media, and 2 to cutaneous infections. Of the local vertebral and paravertebral conditions from which infection spread into the cord, (closed) fracture came first, followed by tuberculous and pyogenic osteomyelitis, and infection in such conditions as meningocele and spina bifida with a communicating sinus. In 10 cases the abscesses were multiple.

Infection may be conveyed to the cord by the spinal arteries, though these are small and arise from their parent trunks at an acute angle; more probably it travels by the vertebral and spinal veins, which communicate with the pelvic veins and the veins of the abdominal and thoracic parietes. Possibly also it may travel in a retrograde manner along the lymphatics of the spinal nerves, thence invading the perivascular spaces; the early appearance of root pains in an intramedullary lesion is a point in favour of this route.

The reasons advanced for the rarity of spinal abscesses are (1) the small volume of the cord in comparison with that of the brain; (2) the small lumen and acute angle of origin of the spinal arteries; and (3) the protected situation of the cord. Some cases running a chronic course may have been diagnosed as transverse myelitis or meningomyelitis and may have ended in a paraplegia not causing death in hospital.

The causative organism was isolated from the abscess in 21 instances. In 9 it was a staphylococcus, in 4 a streptococcus, and in 1 case both were found. Pneumococci and coliform organisms occurred together in 3 cases, actinomyces in 2, and pneumococcus and actinomyces in 1, and in 1 case there was a mixed infection with staphylococci, streptococci, pneumococci, and actinomyces; 1 abscess was sterile (after a course of penicillin and sulphathiazole).

CLINICAL FEATURES

The course may be rapid, with death within a week, and this seems to be usual where septic infarction of the cord follows such conditions as infective endocarditis, bronchopneumonia, or empyema; thus in 2 cases where intramedullary abscess complicated suppurative pulmonary disease, death occurred in three days. It is important, however, to appreciate that in most cases the course is subacute or chronic and that symptoms are evident for weeks or even months before death or (for the fortunate few) operation. Thus in 1 case, in which the primary disease was intrathoracic and in which a cerebral abscess coexisted, the patient survived seven months; while another patient had symptoms for more than two years before coming to operation.

In acute cases backache and root pains are said to be rather less conspicuous than in extradural abscess, and the first symptom is usually paræsthesia in the feet, followed by increasing weakness and a rising level of sensory impairment until the signs of a complete transverse lesion of the cord are present; even then there may still be a further ascent in the sensory level (Elsberg 1941). Paralysis of the sphincters comes early; and in about half the acute cases, after a few days of flaccid paraplegia, signs of meningitis develop. In subacute cases symptoms may be purely motor after the initial root pains, and it is not until the paralysis is almost complete that sensory loss is manifest. In 3 of the reported cases visual impairment due to optic neuritis was the first symptom, preceding the spinal symptoms by as much as a week. In the chronic form of the disease, root pains are nearly always present at the start; the course and the clinical and radiological findings are those of intramedullary spinal tumour; terminal meningitis is not a feature, death occurring as a result of urinary infection, bedsores, or the primary infective condition.

The diagnosis has very rarely been made before the cord was examined; so wherever an intramedullary tumour is encountered at operation the cord should be aspirated and if necessary incised through the posterior median septum.

Examples of Recovery

Evidently the spinal cord has a far greater ability to recover from a space-occupying lesion within its substance than is generally supposed. Notable examples of subacute or chronic abscesses are those of Hitchcock (1917), Woltman and Adson, Walker and Dyke, and Ameli.

In Hitchcock's case a man had noticed numbness and some weakness of the left leg twelve days before admission, becoming worse and being followed by abdominal pain on movement or sitting; three days before admission he had difficulty with micturition. He was found to have septic lesions of the hands and almost complete spastic paraplegia with hypalgesia on the left leg and left side of the abdomen. Numbness soon developed in the right leg, and the paraplegia became flaccid with a sensory level to pin-prick at D 12, though light touch sensibility remained unimpaired. Laminectomy was carried out, but unhappily the cord itself was not punctured, and he died with a large abscess occupying the lower 7 in. of the cord.

Woltman and Adson's patient was a girl of eleven whose legs suddenly became paralysed; she had retention of urine and low pyrexia, and soon developed a bedsore. After three months she made an almost complete spontaneous recovery. Two years after the first episode spastic paraplegia slowly developed in the course of five months, at the end of which time sensory loss with an indefinite level at D 8 was apparent. There was evidence of spinal subarachnoid block; the fluid contained but 2 lymphocytes per c.mm. At operation the dura was found to be bulging and thickened, and from an abscess cavity in the cord, 1·5 cm. long at D 7, pus containing staphylococci of low virulence was obtained. Sensibility began to return to the legs in two weeks; after eight months she could just walk, and sphincter control was normal; and in two years she made a complete recovery.

Walker and Dyke give the history of a girl of three who for a year had had intermittent attacks of headache and vomiting, and, during the month before admission, backache and transient paresis when her pram was jolted. A week before admission she had a severe headache, complained of generalised pains, and lost the use of her legs. She was admitted with pyrexia, signs of meningitis, and a spastic paraplegia, with pain on passive movement but no sensory impairment; there was a small dimple with a single hair in the lower lumbar region, and radiography showed the laminæ of L 4 and 5 to be defective. A lumbar puncture gave, on altering the depth of the needle, two different fluids, one frankly purulent, the other turbid but less proteinous; pneumococci and coliform organisms were grown from both, and staphylococci were grown from the cisternal cerebrospinal fluid (c.s.f.). At the first operation a thick fibrous stalk was traced from the dimple to the dura, and turbid c.s.f. flowed from the incised theca. The temperature fell, but the spasticity increased. Some three weeks later needling revealed thick pus, and at the second operation the lumbar enlargement of the cord was found to be swollen and congested; on incision 12 ml. of pus issued from a cavity 1 cm. wide. After two months she was just able to walk with assistance, and seventeen months later she was apparently normal.

Ameli's patient was a girl of six who eleven months admission had suffered from vulvovaginitis and after eight months the pain grew worse and she devel foot-drop on the left, with absence of the left knee-jerk ankle-jerk but no sensory impairment. Five weeks admission a flaccid paralysis of the right leg developed, she was given penicillin. Paraplegia had become in a further two weeks, with retention of urine; it was a week after this that sensory loss could be detected. puncture supplied evidence of complete spinal block, myelography demonstrated the level of the lesion at the border of the eleventh dorsal vertebra. At operation the was found to be swollen, and 3·5 ml. of pus was and replaced by penicillin solution. Only slight ensued, and the wound was reopened eleven days later, 4 ml. of pus was aspirated. Seventeen days later control micturition was established; after two months she walk; and five months later she was walking with slight difficulty.

THE PRESENT CASE

A married woman, aged 42, was admitted t Atkinson Morley Hospital under Mr. Wylie McKi on Jan. 30, 1948.

History.—Three and a half months previously, while s she suddenly had a severe, burning, tight feeling i lower lumbar region, radiating round the lower abd on both sides; she had a shivering attack, and vomited. constricting sensation diminished, but next evening sh a sharp pain, worse on inspiration, in the left side of the c with shortness of breath but no cough; her temperatur 104°F. Her doctor found signs of consolidation and presc sulphonamides. Cough remained strikingly absent, exce one occasion a week later when she produced a small an of sputum streaked with blood. She spent five weeks in and was free of pain; but she continued to lose weight her periods ceased.

A month before admission she began to get burning p the region of the right iliac crest, right groin, and lef with a feeling of tightness in the lower abdomen; this was worse on lying down, and was very severe if she cou but it was eased by sitting up with a pillow behin lumbar spine. A week later she noticed steadily difficulty in raising the left leg to climb stairs, and symptom was followed by pains shooting down the borders of both thighs. A week before admission the leg became weak, and next day, while getting off a c she developed a very severe pain in the left buttock, a deep boring pain in the rectum. There was considerable in initiating micturition, and at this stage apparently and urethral sensation were lost.

Four days before admission the buttocks were numb, legs were becoming rapidly weaker, and wasting was appa The root pains persisted, and she had retention of urine overflow; she was incontinent of fæces once, and the became constipated.

Investigation.—She was a thin pale woman with a temp ture of 100°F, but no abnormality in the cardiovascula respiratory systems. Cranial nerves and upper limbs nor Abdominal reflexes present; no umbilical displacem bladder distended to umbilicus with dribbling incontine The lower limbs were hypotonic; there was moderate was of the quadriceps and buttocks on both sides, and ma wasting of the anterior tibial muscles. She had bilateral drop, and could only just lift each leg a few inches off bed. The left knee-jerk was diminished, both ankle-j were much diminished, and the plantar responses were flo There was impairment of sensibility to light touch, an painful and thermal stimuli, over the buttocks and perine down the backs of the thighs and legs, and on the soles of feet, while joint sense appeared to be unimpaired.

At lumbar puncture the c.s.f. issued at low pressure coagulated almost immediately, and contained 1200 protein per 100 ml. with 100 red cells and 5 white cells c.mm. Radiography showed no abnormality in the chest widening of the interpedicular space of the twelfth dor and slight widening of the interpedicular space of the lumbar, vertebræ. On Jan. 31 myelography was performed the cisternal route using 3 ml. of 'Ethiodan.' The cont material was held up completely at the lower border of D in the lateral view the lesion could be seen to extend up as the middle of the body of D 12. In 48 hours no contrast :erial had passed downwards. The cisternal C.S.F. contained ·hite cells (90% polymorphs), 15 mg. of protein per 100 ml., normal quantities of sugar and chloride.

'peration.—On Feb. 2 a laminectomy was performed by Valentine Logue. The dura was found to be tense, with iost no extradural fat; the subarachnoid space was iterated. The last $1^1/_2$ in. of the cord and conus were ›llen and had a yellowish mottling, while from the conus ›inkish-grey "tumour," 2 in. long, extended downwards l slightly to the right, to end in a yellow bulbous extremity. piration of the swollen conus and of the bulbous lower end [illegible] lent material, from which *Staphylo-* [illegible] coagulase-positive) grew on culture. e nerve-roots were slightly adherent to the swelling but ıld be dissected off. A portion of the mass was taken for ;tological examination. The dura could not be closed, and › exposed surface of the cord was covered with an almost ntinuous sheet of fibrin foam before closure of the wound in ıltiple layers.

Section of the minute fragment of tissue removed showed it consist of dense fibrous tissue infiltrated with small round lls.

Postoperative Progress.—Tidal drainage was instituted. In ı days the patient received 2,740,000 units of penicillin ıtramuscular) and 'Sulphamezathine' 34 g. The urine was avily infected with *Bacterium coli*. The temperature conıued at 101°F until the third day, and ranged between and 100°F for fifty-five days. Severe pains in the thighs ntinued for sixteen days. Tidal drainage was discontinued ter thirty-four days, though control of the bladder was not tisfactory until eleven weeks after the operation. Four onths after operation she could just walk, though she owed considerable weakness in all muscle groups, and lateral foot-drop. She was then sent home.

Seen nine months after the operation she said there had been eady improvement in the power of her legs, and she was ›le to dispense with her toe-springs; she could get up and ›wn stairs with the aid of a stick, and was able to do her own ›oking; only when sitting for a long time did she notice ımbness of the buttocks. She still suffered from occasional ıooting pains in the left buttock and the front of the left ıigh, together with pins-and-needles in the outer side of the mb. She looked remarkably well.

The feet were cyanosed and cold, and there was wasting f the anterior tibial and peroneal muscles, and the intrinsic ıuscles of the feet, more on the right than the left; both mbs were hypotonic. The wasted muscles were weak. The ft knee-jerk was present, the right diminished; both ankle›rks were absent, and no response was obtained on plantar ;imulation. There was a small area of hypalgesia on both uttocks, including the perineum, and there was hypalgesia nd hypæsthesia over the lower and outer part of both legs, ıe soles, and the dorsum of the feet (except for a small medial ;rip). Sense of position and passive movement was slightly npaired in the feet. Control of the sphincters was ;tisfactory, but urinary infection was still present.

SUMMARY

A case of metastatic intramedullary abscess affecting he lumbosacral enlargement of the spinal cord is escribed. Operation considerably reduced the patient's 'araplegia.

Four other reported cases with survival are sumıarised.

Early recognition of this condition is desirable now that he chances of success at operation have improved.

I am indebted to Mr. Wylie McKissock and to Mr. Valentine ogue for permission to publish this case, and to Dr. J. W. D. ull for the radiological reports.

FULMINATING APYREXIAL POSTPARTUM STREPTOCOCCAL PERITONITIS

L. N. JACKSON
M.C., D.M. Oxfd

MARGARET H. JACKSON
M.B. Lond., D. Obst. R.C.O.G.

COMPARED to the commoner forms of puerperal sepsis, such as pelvic infection and septicæmia, postpartum general peritonitis has been reported remarkably seldom. The condition is of course mentioned in general surveys such as those of Wyatt (1932) and Ramsay and Dolphin (1946). Wyatt, from the London County Council's puerperal sepsis unit at the North-Western Hospital, reported 12 cases of general peritonitis (8 of them fatal) among 242 patients with puerperal sepsis admitted: in 11 a hæmolytic streptococcus was grown in pure culture, while in the other case, which recovered, the causative organism was a pneumococcus. Ramsay and Dolphin quote 24 cases of general peritonitis (with 15 deaths) in the same unit in the seven years 1937–44. They regard it as still the most fatal of all puerperal complications, though the sulphonamides and penicillin have improved the chances of recovery.

We have found only five papers describing cases in detail. Banerji (1938) reports 4, of which 2 were fatal. Contamin (1938) and Keller (1935) each report 2, which recovered, and Ginglinger (1938) 1 which did not. Courtois and Phillipe (1938) who report the largest series (16) point out that fever may be slight in proportion to the pulse-rate. All writers emphasise the importance of early diagnosis, laparotomy, and drainage.

In the case we record here the diagnosis was not made before death, the difficulty of diagnosis being enhanced by the absence of fever and rigors throughout the illness. We have found no previous mention of an apyrexial course.

CLINICAL HISTORY

A.B., aged 27 when she died, had married a farmer in 1945. Her first pregnancy, which was uneventful, ended at term with a normal labour in 1946. An episiotomy was performed which was repaired with three sutures, but there was no other obstetric interference. Because of invaginated and sore nipples, breast-feeding had to be abandoned after five weeks, and despite active treatment, including sulphonamides, a breast abscess developed and had to be drained. Recovery was uneventful. The patient stated that she had always been strong and had had no serious illnesses, but that her resistance to minor infections was poor.

Finding herself pregnant again she consulted the doctor in August, 1947. During this second pregnancy she did not feel so generally fit as during her first, but her blood-pressure remained within normal limits and her urine was normal. In February, 1948, twins were diagnosed, and their presence was confirmed by radiography. Both fœtuses were vertex presentations. Labour started spontaneously at term on March 11, and the patient was conveyed by car from her own home to a nursing-home, a distance of 12 miles. A few days previously she had had a slight cold and sore throat. One of us (M. H. J.) was called to the nursing-home soon after 11 P.M. and remained with the patient till labour was complete, about $1^1/_2$ hours later. Except that she received gas-and-air analgesia intermittently and that both bags of membranes were unusually tough and had to be ruptured as they presented at the introitus, labour was perfectly normal and unassisted. Between the births of the two healthy infants, both females, the first weighing 7 lb. and the second 6 lb. 7 oz., there was an interval of perhaps five minutes, or a little more. During the second stage the patient had only two pains. A superficial skin tear in the region of the old episiotomy scar required two stitches. The third stage, except that a little fundal pressure was necessary, was quite normal and blood-loss was very moderate. A routine intramuscular injection of ergometrine was given on completion of the third stage.

One of us (M. H. J.) saw her on the evening of the next day (March 12) about 18 hours after delivery, and was told that she had been complaining of "after pains" most of the day. She had attempted to suckle the infants, but her nipples were already becoming sore. Her temperature was 98·4°F; pulse-rate 80; respirations 20. A dose of calcium aspirin was ordered. Next morning her temperature was 97·6°F; pulse-rate 72; respirations 20. She said that her nipples were sore, and in view of the previous history breast-feeding was abandoned. More aspirin, and also stilbœstrol, were ordered. She still complained of lower abdominal discomfort and intermittent cramping pain; she resented palpation but there was no rigidity. The same evening the temperature was still normal (98·4°F), and the respiration-rate was 22; but her pulse-rate had risen to 120. For the first time she looked ill, being pale and slightly cyanosed. There had also been difficulty in passing urine; 8 oz. was withdrawn by catheter. Her bowels were not opened. There was no vomiting. The lochia were clean and inoffensive, the stitch area clean, and the breasts comfortable. The abdomen was slightly distended and tympanitic. There was no rigidity although there was generalised abdominal tenderness.

The clinical picture was more suggestive of mild shock than of infection. Nevertheless, in view of the abdominal tenderness and increased pulse-rate, sulphadiazine was ordered and also 'Omnopon' and scopolamine for the relief of pain.

Next morning (March 14) she was clearly very much worse. Catheterisation yielded 6 oz. urine. She was pale, restless, and cyanosed. The abdomen was distended, with a central area of tympanites and shifting dullness in the flanks. There was slight generalised abdominal rigidity. Temperature 98·6°F; respirations 40; pulse uncountable. Another opinion was sought, but before it could be obtained the patient had an immense vomit and died within a few minutes. At no time during the whole course of the illness did she show any pyrexia. The condition suggested some such abdominal catastrophe as massive mesenteric thrombosis, volvulus, or postpartum rupture of the uterus.

POST-MORTEM FINDINGS

At necropsy the same day more than 2 pints of turbid and quite inoffensive fluid, not bloodstained, was found in the peritoneal cavity; it was thin in the upper abdomen but thicker in the pelvis. The stomach and first part of the small intestine were greatly distended. The last 6 ft. of small intestine was shrunken and empty and the surface was brightly injected. The peritoneum had not lost its gloss and was not flecked with fibrin or pus. The appendix appeared normal. The large intestine contained firm fæces and was not particularly collapsed. There was neither volvulus nor herniation of the intestine. No antemortem thrombus was found in the pelvic or mesenteric vessels. There was passive congestion of both pulmonary bases but no other abnormality in the thorax. No pulmonary thrombosis was found. The liver, kidneys, pancreas, and spleen appeared normal. The fimbriæ and ampullæ were deeply congested. Dr. C. P. Warren, pathologist to the Royal Devon and Exeter Hospital, reported as follows. "*Peritoneal fluid.* (*a*) Centrifuged deposit. Gram film: many pus cells. Many short-chain streptococci. (*b*) Cultures: hæmolytic streptococci of group A (Lancefield). *Uterus and appendages.* A bulky postpartum uterus (9×5×4 in.) with a dilated os and injected ovaries and fallopian tubes. The fundus contains small blood-clots and the endometrium is soft, shaggy, and oozing. There is no evidence of retained placental fragments. There are a few small portions of membrane."

POSSIBLE SOURCE OF INFECTION

In the evening of the day on which the patient died the maternity nurse who attended her developed a sore throat. On the following day one of us (M. H. J.) who made the post-mortem examination also developed a mild sore throat. On the day after the patient's death swabs were taken from the throats of the husband, doctor, and nursing staff, and were examined and cultured by Dr. B. Moore at the Public Health Laboratory, Exeter. The throats of the doctor (M. H. J.) and of the maternity nurse in attendance, but of none of the rest of the staff, were found to be infected with a streptococcus of group A, apparently identical with the organism found in the patient's peritoneal fluid. The group-A streptococcal strains isolated from the throats of the doctor and of the maternity nurse, and from the patient's peritoneal fluid, were examined by the Streptococcal Reference Laboratory, Oxford, and were reported as being probably of the same type, in that they agglutinated with G types 5, 17, 22, and 25 sera.

The twin infants were put under the charge of ano nurse, who conveyed them to her own home. A days after she had done so she developed a mild strep coccal tonsillitis, and her sister, who had been away another part of the county *and who joined her at* a few days later, also developed a severe strept tonsillitis, soon after reaching home, which kept away from work for about six weeks. The hæmoly streptococcus isolated from these throats was not typ for the doctor who took the swabs was not aware at time that the nurses had any association with the reported in this paper.

It is impossible to decide in retrospect the source of infection with any degree of finality. In t great majority of puerperal infections the infecti organism is held to be derived from the medical nursing attendant or from a member of the household. Dr. Dora Colebrook found, however, that 12% of cases the organism came from the patient's throat (Colebrook 1935). The clinical sequence above suggests that the patient's throat may have the source of infection here; for she had a sore t before admission to the nursing-home whereas symptoms developed in the attendants after the ev

It is with a proper sense of humility that we r this case, in the hope that our experience may put o on their guard.

ANKYLOSING SPONDYLITIS

IN ALL THREE CHILDREN OF ONE FAM

WILLIAM TEGNER
B.M. Oxfd M.R.C.P.
PHYSICIAN-IN-CHARGE AND DIRECTOR, DEPARTMENT PHYSICAL MEDICINE, LONDON HOSPITAL

KENNETH LLOYD
M.B. Lond. M.R.C.P.
FIRST ASSISTANT IN THE DEPARTMENT

ANKYLOSING spondylitis is a disease of unk ætiology. Its familial incidence has not been exte studied, but there is growing evidence that fa factors play a part in its development. Thus Ca (1947) says "the familial history is *significant* is *inadequately emphasised in the English litera* Commenting on a paper by Polley and Slocumb (Freyberg points out "that a large percentage spondylitis tell of their brothers, fathers or sons who true spondylitis. Often it is not recognised." he says "we found families in which the female se affected also—father and daughter, or a son an mother would have spondylitis." Polley and Slo themselves noted a definite family history in 0·4% of 1035 cases, while Simpson and Steve (1949) figure is 1·0% of 1200 cases.

There have been several reports on ankyl spondylitis in brothers. Ray (1932) described male who were both affected. Dawson (1935) q Burckhardt's report of a family in which the mothe four sons all had ankylosing spondylitis. Steche Hauser (1946) described the disease in two bro and mentioned a similar case recorded by Weil Allolio. Stauffer and Moffett (1946), writing o "pedigree of ankylosing spondylitis," reported ase in a grandfather, father, and son. (Buckley 15) says that “over 90 per cent.” of patients suffering n this condition are males.)

Ve have not found any previous report of ankylosing ndylitis in all three members of one generation.

CASE-RECORDS

ase 1.—A man, aged 25, a draughtsman, was referred ospital because of low back pain present practically for years. The pain persisted at rest, often radiated m one or both thighs as far as the knees, and was gravated by coughing and sneezing; at night some relief s obtained only by getting up and exercising the back. s general health was good and he had not lost much weight. He was a well-covered young man standing with a slight racic slump and a loss of the normal lumbar lordosis. most no lumbar movement; chest expansion 1 in. at histernal level; slight limitation of neck and hips; other nts normal. Erythrocyte-sedimentation rate (Wintrobe) mm. in one hour. Radiography: sacroiliac joints fused; cification in lateral longitudinal ligaments in upper lumbar d dorsal regions.

The patient said he had one sister and one brother. e former was “rigid from top to bottom”; the tter suffered from recurrent backache. No such mplaint was known in other relations.

Case 2.—The sister, aged 31, was asked to come up for amination. She said she had bad low back pain and atica at the age of 15, but nevertheless embarked a year later a nursing career. At 19 she had an acute flare-up of ckache with pains in all joints; the latter cleared gradually ter some weeks in bed, but she was left with a very stiff ck. Backache persisted, chiefly in the dorsal region, but e later resumed nursing at a smaller hospital where the ties were supposedly less arduous. By the age of 25 e symptoms reached the neck and shoulders; she found e could not do heavy lifting and finally gave up nursing. nce then the pain has gradually decreased, and now she ly gets an ache in the dorsal region associated with overwork d muscular fatigue.

She stands erect in a fair position, but the whole spine is mpletely rigid; the left shoulder is slightly limited in range movement but painless. All other joints are normal d chest expansion is ½ in. at the xiphisternal level. Radioaphy: bony ankylosis of the sacroiliac joints; fusion of all mbar vertebræ; thoracic vertebræ also affected.

Case 3.—The brother was also asked to come up for amination. He is 32, and says that five years ago he arted to get attacks of “lumbago” every two or three onths; the pain lasted only a few hours and he was able “work it off,” being symptom-free in the intervals. This ate of affairs continued for about a year, after which he d a year with no symptoms. Three years ago the attacks of mbago returned, but lasted weeks or months at a time with riable free intervals. The pain was aggravated by coughing d sneezing and by gardening; it was eased by rest but not y heat or liniments. Recently the severity of the attacks as greatly diminished and at the moment has been free from in for about two months. He is well and active, has a erical job, and plays badminton. On examination, he is and muscular; the spine and all joints move painlessly rough a full range, the only abnormality discovered being me tenderness to pressure over the left sacroiliac area. adiography shows an unequivocal bilateral sacro-iliitis pical of ankylosing spondylitis. E.S.R. (Wintrobe) 20 mm. one hour.

DISCUSSION

Davison et al. (1947) reported an increased urinary cretion of 17-ketosteroids in ankylosing spondylitis. ater (1949) they stated that, though deep X-ray erapy may prove clinically effective, clinical improveent is not associated with decrease in ketosteroid cretion. Hench et al. (1949) have described the use 17-hydroxy-11-dehydrocorticosterone (compound E) rheumatoid arthritis; of their 14 patients 1 had rheumatoid spondylitis,” the American synonym for kylosing spondylitis. All his patients had low ketoeroid excretions, and the excretion level was further reduced by the use of the new compound which proved so successful in the treatment of rheumatoid arthritis. The relation of ankylosing spondylitis and rheumatoid arthritis, and their connexion with compound E, need further investigation in the light of this new work.

The apparent relation of ankylosing spondylitis to 17-ketosteroid metabolism may have a bearing on its familial incidence. In gout we have a metabolic disease with a strong family tendency in which the males are prone to develop gouty arthritis when some trigger mechanism is brought into play. Perhaps similarly there is in certain families a spondylitic tendency when certain factors operate: the males are likely to develop ankylosing spondylitis and the females may also do so if the factors are sufficiently powerful.

It is worth noting that in our original patient's brother the ankylosing spondylitis would have gone unrecognised if he had not been summoned for examination.

MERCAPTAN IN THE BREATH OF PATIENTS WITH SEVERE LIVER DISEASE

L. S. P. Davidson
M.D. Edin., F.R.C.P., F.R.C.P.E., F.R.S.E.
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF EDINBURGH

In four cases of severe fatal liver disease seen in the last few years, all terminating in cholæmia, the breath had an extraordinarily penetrating odour, which was quite distinctive and in three of the cases could be detected on approaching the ward in which the patient was being nursed. This smell could best be described as like that of a mixture of rotten eggs and garlic, and was closely similar to that of mercaptan. I have not been able to find any published reference to the production

ANALYSIS OF CASES

—	Case 1	Case 2	Case 3	Case 4
Sex and age (yr.)	F.30	M.22	M.10	M.31

Kidney ..	Advanced cloudy swelling and necrosis	..	Advanced cloudy swelling	Advanced cloudy swelling and necrosis

of mercaptan in the breath of patients with fatal hepatic necrosis, and the present cases are recorded in the hope of gaining further information. The salient features of the four cases are summarised in the accompanying table.

Reference is occasionally made to fœtor hepaticus or amin breath, and Lichtman[1] has briefly reviewed this. He described it as a feature of severe liver damage, and mentioned reports in which it was stated that the fœtor hepaticus was present in 20% of a series of cases of catarrhal jaundice or cirrhosis with jaundice, and in 9 out of 16 cases of liver atrophy. This odour is said to resemble that of indole and has been given the name "amin," but no suggestion is made in any of these reports that a sulphur compound might be responsible. Further, the high incidence of this fœtor hepaticus contrasts with the rarity of this present observation and suggests that they are different phenomena. The odour in the cases described here was sufficiently distinctive to exclude any possibility of its having passed unnoted in any other of the many cases of liver disease encountered. Many of these latter do in fact have fœtor, but of quite a different character, resembling the odour often found in uræmia and other toxæmic states. The chemical identity of the responsible substance has not yet been established.

The most likely origin of a mercaptan or similar compound would be the sulphur-containing amino-acids methionine and cystine. It was thought at one time that methionine therapy might have been the cause, but the table shows that this was not so. Normally the sulphur from these amino-acids is excreted in the urine as sulphates or as "neutral" sulphur, which latter is known to contain traces of a mercaptan (di-ethyl thio-alcohol) and an alkyl sulphide (di-ethyl thio-ether). These, or related substances, would give rise to the odour which is being described, if produced in greater than normal quantities. It could be postulated that in severe liver failure, under certain conditions, there might be excessive or abnormal katabolism of sulphur-containing amino-acids of tissues or food leading to excessive production of these thio-compounds.

INHERITANCE OF NODULAR GOITRE

REPORT OF A FAMILY

W. P. U. Jackson
M.A., M.D. Camb., M.R.C.P., D.C.H.
LATE ASSISTANT PHYSICIAN, SELLY OAK HOSPITAL, BIRMINGHAM

It is evident that hereditary factors in simple goitre can be easily studied only in non-endemic areas, since in endemic areas many members of the same family may develop goitre for environmental reasons. Brain (1926) considered that there was also a definite hereditary
factor because some families in goitrous areas
disproportionately affected, some members c
families who were born and bred in non-endem
were affected, and hereditary goitre sometimes
in families in non-goitrous areas. Joll (1932)
that marriage between two goitrous people in an
area produced a higher proportion of goitrous
than when only one parent was affected. Gardi
(1934) reported a family from an endemic
which all the females who moved to non
areas at marriage developed goitres later, a
of their children were also affected. Crotti
and Milligan (1926) reported similar families.
(1945), on the other hand, found no evid
inherited traits on detailed examination of the
trees of 50 cases of nodular (toxic and no
goitre.

In view of the doubt of the importance of h
factors in simple goitre, and of the type of inh
involved, the present family tree (see figure) seem
reporting. The tendency of goitre in this fa
become toxic is also of interest. So far as
ascertained, no members of it had been born in
in an endemic goitre area, and all resided in
districts. The first generation was born and
Leicester, and the woman who initiated the
under discussion moved to West Birmingham a
period during her childbearing age, with the resu
some of the second generation were born in L
and later ones in Birmingham—*it is not known*
when the removal took place. All of the thi
fourth generations were born and reared in
except the final living member (no. 12), whose
had moved to Worcester. None of the spouses
married members of the family were affected a
are not included in the chart. All goitrous
had had their enlarged thyroids as long as the
remember, except that no. 9 first noticed hers
age of twenty-three and no. 12 at fourteen.
person, therefore, who developed thyrotoxicosis

ition a recessive gene is probably involved (Martin).

SUMMARY

family is reported in which eleven females and one have developed nodular goitres. None have ever in an endemic area.

this family there is also a (presumably inherited) ency for the goitres to become toxic, as shown the development of hyperthyroidism in five ibers.

should like to thank Professor Fisher for his comments t the family tree, and Mr. R. P. S. Kelman, medical superident, Selly Oak Hospital, for permission to make use ospital records.

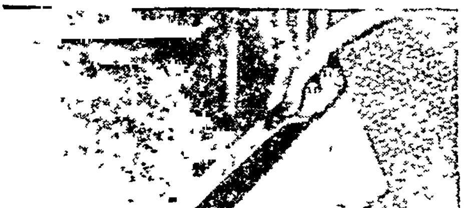
New Inventions

OCKING-HOLDER FOR THE STIFF-JOINTED

NE of the greatest hardships of the man or woman ı severe osteo-arthritis or ankylosis of the hip or knee- t is the inability to put on their socks or stockings shoes unaided. A patient at the Charterhouse ic, infuriated at the daily struggle, devised the ple apparatus here illustrated and found it highly cessful.

t consists of two light strips of metal joined as a n the flat, the shorter piece being curved into a half nd. This half round is furnished with three studs, ced one in the centre and one at either end; and ee lengths of elastic, fixed by a screw to the handle, ry ordinary suspender fastenings which will clip on to studs.



The user has only to fix the top of the stocking or sock the three studs when it will hang in an open loop into ich the foot can be easily inserted and the whole wn up the leg. The handle or long end, shaped e a shoe-horn, renders equally easy the slipping on an elastic-sided shoe or a court shoe. Unfortunately has not so far been possible to devise an instrument draw tight and tie shoe laces.

The instrument is made by Messrs. Down Bros. and Mayer & elps Ltd., of London.

Skeletal Tuberculosis

VINCENTE SANCHIS OLMOS, M.D., assistant director of the Instituto Nacional de Reeducacion de Invalidos de Carabanchel Bajo, Madrid, Spain. Translated by JOHN G. KUHNS, M.D. Baltimore: Williams & Wilkins. London: Baillière, Tindall, and Cox. 1948. Pp. 261. 27*s*. 6*d*.

IT is doubtful whether there is any infective condition more unpredictable in its behaviour than tuberculosis of bones and joints. The initial lesions are diverse—the puffy tuberculous knee, caries sicca of the shoulder, the expansile marrow infection of a phalanx and the metaphyseal spinal lesion, with little bone-destruction yet the source of an enormous cold abscess. The course of the disease is almost equally variable. Often there is a regular progression through a phase of destruction to quiescence, followed by recalcification leading to fibrous and sometimes bony ankylosis of the joint. Yet while one lesion is healing another may appear elsewhere and run its course independently. Sometimes the disease advances relentlessly like a malignant growth, and the battle is a losing one from the start. These irregularities, often complicated still further by the appearance of visceral lesions, compel the clinician to be vigilant in his management of the patient and cautious in giving a prognosis.

In the face of these vagaries, the attitude of most British workers has been one of quiet resignation. Intent on the proper conduct of treatment, in itself a difficult enough task, they have not spent—or, as some might say, wasted—time on trying to explain the phenomena of skeletal tuberculosis, which after all are but part of the whole problem of the host-parasite relationship in tuberculous disease. And tuberculosis is only one of many infective diseases in which the same problem arises in one form or another. Yet it must be confessed that in this respect orthopædic surgeons have lagged behind their colleagues dealing with pulmonary disease. Dr. Sanchis-Olmos's book is a welcome departure from this now almost traditional empiricism. He has done his best to apply theories concerning the pathology of tuberculosis to the behaviour of skeletal lesions; he gives particular prominence to the views of Gonzalez-Aguilar, an Argentine worker, and contributes a number of ideas of his own. His evidence is derived from experience in Spain, and from a detailed analysis of the excellent records of the Peabody Home for Crippled Children which he studied during the course of a visit to Boston.

The first quarter of his book is concerned with pathology; the second with the conventional topics of radiological examination, symptoms, signs, diagnosis, prognosis, and treatment: the other half of the book is a description of the disease as it affects the various parts of the skeleton. The first is by far the most important section, though the other two are unusually interesting in that they are permeated by the ideas and terminology to which the reader is introduced in the section on pathology. Skeletal tuberculosis, Dr. Sanchis-Olmos says, may present as an osteitis or synovitis having one of three forms—exudative, granular, or caseous. (A lesion involving both bone and joint is called *osteo-arthritis*, a logical term, but an unfortunate one for the British reader.) The three types of inflammatory change, it is explained, are not always sharply defined: an exudative process, for example, may be followed by caseation or by granulation. The local lesion also shows an evolutionary pattern in which five phases are distinguishable. The reaction of the patient to his infection is even more complex, there being no less than seven possible phases in the struggle between the host and the parasite, with anything up to five possible events in the four phases following primary infection.

These classifications, derived in part from the theories of earlier workers, are undoubtedly a valiant attempt to explain the various possible sequences of events, which most of us find incomprehensible. They remind one a little of Karl Marx's analysis of human affairs, and seem to be about equally insusceptible of proof. But whereas the average exegesis of Marxian doctrine makes some impression on even the hardened unbeliever, Dr. Sanchis-Olmos leaves even the sympathetic reader bewildered. That there is an explanation of these events nobody can doubt, and a thoughtful clinician can contribute much by careful observation and analysis of his findings; cautious speculation, too, is not out of place. But any hypothesis, even if it is wrong, should at least appear to bring some semblance of order out of chaos. Perhaps the author. in his anxiety to give due weight to the views of others, has not been dogmatic enough: it is certain that he has not been well served by his translator. The result is that his work, although intrinsically attractive, is hardly likely to appeal to those whom, presumably, he is particularly addressing—namely, orthopædic surgeons who are interested in skeletal tuberculosis. Here is an example of the sort of writing that spoils the book: "It (a régime of treatment) has been opposed only by one school, that of Gonzalez-Aguilar, which attempts to establish scientifically the pathogenic and anatomopathologic concepts on which the theory of the biopathologic unity of tuberculosis must be based."

Yet, in spite of its imperfections, this work must be commended to the British reader. It is an indirect and well-deserved rebuke of our empiricism, and perhaps it will provoke some of our own authorities on skeletal tuberculosis to go more deeply into the natural history of what is still, unfortunately, a fairly common and always serious disease.

Conference on Metabolic Aspects of Convalescence

Editor: EDWARD C. REIFENSTEIN, jun., M.D. Transactions of 16th meeting, Oct. 27–28, 1947, and 17th meeting, March 29–30, 1948. New York: Josiah Macy, jun. Foundation. 1949. Pp. 168. $3. Pp. 246. $4.

THE first of these conferences was held in September, 1942, and there have been two or three each year since that time. The published reports contain the original contributions of the speakers and also a full account of the discussions. These consist largely of comments, questions, and verbatim interjections which do not always enhance the interest of the reports to people reading them some months or years later. The general title may be a little misleading to doctors accustomed to discussions on the same subject in this country, for much of the work described and discussed has been carried out on rats; and little of it has any direct bearing on convalescence as the word is usually interpreted here. The volumes really consist of a collection of short descriptions of original work, mostly of a biochemical nature, ranging from studies of blood arginase to adrenogenital hormones and from protein synthesis to citric acid. They will be scanned by scientific workers in search of information bearing on their subject, and many will be found to have considerable interest.

The Chest and Heart

Editors: J. ARTHUR MYERS, PH.D., M.D., professor of medicine and preventive medicine and public health, University of Minnesota, Minneapolis; C. A. MCKINLAY, M.D., associate professor of medicine in the university. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1948. In two vols. Pp. 1850. £7 7*s*.

Professor Myers himself contributes something over 300 pages to this laborious work. From the preface it seems that the book is intended for medical students, for physicians in general practice, and for those in "special fields whose diagnostic and therapeutic problems at times are related to diseases and conditions of the chest and heart." Some of the sections can only be for elementary students, for there is great elaboration of detail in physical examination. As a text for more senior undergraduates it is too long; it does not sufficiently explain which things are important and which are not; and the index, despite its 60 pages, is gravely inadequate. But there are good sections on pulmonary œdema and pulmonary embolism, and a fascinating one on the chemistry of the tubercle bacillus. Boeck's sarcoidosis is well covered, and there is a reasoned statement of the position in regard to "acute pneumonitis." Adenoma of the bronchus receives rather scant mention: and doubts will be felt about the statement that treatment of the "so-called adenoma of the bronchus can be best carried out through the bronchoscope." ends with a long article on thoracoplasty. In are the sections on non-pulmonary tuberculosis (inc abdominal, urogenital, gynæcological, eye, and localisations), the whole of the heart section, and a appendix on the pathogenesis of tuberculosis. heart section is well illustrated, and the artic coronary sclerosis one of the best of its kind. I developments in the surgical treatment of conditions are discussed. The book covers much t but not as much as its size would suggest. It lies where between an elementary textbook for stu didactic in nature, and a major reference wo consultation, and it suffers from the faults of any with a large number of contributors. That is not that it does not contain much wisdom and the of a long experience.

Synopsis of Psychosomatic Diagnosis and T

FLANDERS DUNBAR, M.D. London: Henry 1948. Pp. 501. 32*s*. 6*d*.

"SYNOPSIS" is surely not the right word to de this compilation, for besides quotations from d sources—there are 432 references in the bibliogra it has many case-histories replete with trivial d Apart from those containing introductory materia chapters follow the same order as those of the edition of Osler's *Textbook of Medicine*, which the designed to supplement. The psychological aspe disease are of great importance, but it is doubtful wh Dr. Dunbar's confident psycho-analytic interpreta and sometimes uncritical assertions, will further recognition at any rate among physicians.

Functional Localisation in the Frontal Lobes Cerebellum (London: Oxford University Press. 1949. P 15*s*.).—Those who were privileged to hear Dr. John F. F of Yale, speaking at Birmingham last year—and p even more those who were not so privileged—will rej have his William Withering memorial lectures[1] in form. Neurosurgeons and psychiatrists will be imp by the appeal he makes, in his preface, for cauti leucotomy operations, lest they allow their zeal to their knowledge of function. More, "*If they would o on one side of the brain at a time and make small (which could later be enlarged should this be indic fundamental information will be secured which it be difficult or impossible to obtain from the experin animal.*" What we know already of the basic physiol data is set out in all its intricate detail in this book.

Science, Servant of Man: a Layman's Primer fo Age of Science (London: Sigma. 1949. Pp. 362. 15 By relating the history of the discovery of auxins and application to selective weed-killing, to the productio roots in cuttings of plants, and to the prevention of from falling off the trees too early; the electromag theory and its application to radio and radar; the disco of polymerisation and its application to the synthes rubber and 'Nylon'; the discovery of blood-groups and forensic application as paternity tests; and the classific of foraminifera and its use in prospecting for oil, M Bernard Cohen, instructor in the history of science general education at Harvard University, shows that scie discovery cannot be controlled by planning. "Succe planning necessitates some foreknowledge of the eve result—a meta-science transcending human limitati He maintains that the only way in which planning ca applied to science is not by limiting but by extendin scope of free research and in making use of the resu discoveries. Had planning been in control of scie research a few years ago, he says, we should still be wi penicillin and sulphonamides. He subscribes to Con proposals to provide an educational system which offers equ of opportunity, to make sure that there are plenty of petitive scientific groups, and to beware of instituting dictatorial planning board. He also considers that scientists must be educated to understand what scienc so that every taxpayer will realise his responsibility to scientists their requisite freedom in research. This, in is the main object of his book.

THE GENTLE GIANT

'Albucid' Soluble in Ocular Therapeutics

FOR TISSUE of the highest sensitivity it is essential that local chemotherapy be affected by agents free from irritation. 'Albucid' Soluble Eye Drops are adjusted to pH 7.4 and are thus free from irritating alkalinity. High therapeutic efficiency, combined with ready solubility and very low toxicity, makes 'Albucid' Soluble the agent of choice in most eye infections. 'Albucid' Soluble Eye Ointments, containing 'Albucid' Soluble in a neutral cream base, are available for the treatment of infections of the eye and lids, where a slower and more prolonged absorption may be considered advantageous.

'ALBUCID' SOLUBLE

SULPHACETAMIDE SODIUM

EYE DROPS 10% and 30% in bottles of ½ oz.

EYE OINTMENT 2½%, 6% and 10% in tubes of 60 grains and 25 grams.

BRITISH SCHERING
LIMITED

167/169 GREAT PORTLAND STREET
LONDON, W.1

IN THE GLAXO TRADITION

From the range of Glaxo pharmaceutical preparations we present a selection of three products — each backed by the customary careful and studied research of our laboratories.

For the treatment of the most common of deficiency conditions—anaemia due to lack of iron—**FERSOLATE** tablets (ferrous sulphate with additional haemopoietic stimulants) have long been accepted as a logical prescription. In addition to the specific effect of quickly regenerating the haemoglobin content of the blood, a simple course of Fersolate tablets will frequently bring a marked improvement to the patient's general well-being.

OSTOCALCIUM (calcium and vitamin D tablets), well known for its specific uses in the winter has, in fact, important applications throughout the year. In these summer months it is often of real assistance in the treatment of urticaria and other prevalent rashes. And, at all times, Ostocalcium is a wise supplement for the pregnant and nursing mother, on whose calcium reserves such great demands are made.

In immunisation, **DIPHTHERIA-PERTUSSIS PROPHYLACTIC *GLAXO*** offers a convenient weapon against both diphtheria and whooping cough. By combining *two* antigens in a single preparation, Diphtheria-Pertussis Prophylactic *Glaxo* saves the doctor a considerable amount of time, and subjects his young patients to a minimum of discomfort.

FERSOLATE In tubes of 100 tablets **OSTOCALCIUM** In bottles of 50, & tins of 100 tablets

DIPHTHERIA-PERTUSSIS PROPHYLACTIC *GLAXO* In rubber-capped bottles: 2·5 cc., 5 cc. & 10 cc

THE LANCET

LONDON: SATURDAY, JULY 30, 1949

Dangers of Uniformity

It has long been apparent that one of the effects instituting central control over the formerly dependent unit is a loss of elasticity and of power respond to the diversity of local circumstances. ut it is only now beginning to be realised just what is means. All over the country those who administer e hospitals are waking up to find themselves werless to make common-sense adjustments to laries and wages of hospital staff of every kind. hey are not allowed to pay less than the rates laid wn by the Whitley Councils; that is endurable, for is the intentional result of the organisation of hospital orkers through their professional organisations and ade unions. But now, under the new dispensation, ey are not allowed to pay more, it would never , it is argued, for hospitals dependent on the xchequer to bid against each other; therefore all ust conform and pay the standard rate.

The present understanding that the existing rates e in fact standard rates is open to two important es of criticism which will have to be met. sistence on the rule is laying the hospital services en to the charge of sheer inefficiency. In many lds, hospitals have to compete with commercial nployers, and are subject to the limitations of the cality in which they are situated. If a new factory mes and sits down next door they must be in position to make some response. Circumstances of is kind were difficult enough for the hospitals before e appointed day, for their power of response was en limited. But when it really mattered—when important worker like a cook was in question something could be done. Under the new dispensan that ability to respond has disappeared altogether. would be easy to pile up examples of this kind of efficiency, of which the handicap as against the mmercial competitor is merely one aspect. From other angle it is clear that the rule of uniformity courages all the best personnel to congregate in e most favoured hospital or the areas most pleasant live in. All this adds up to a serious charge of sheer efficiency.

But there is a second line of thought, which is rhaps not quite so obvious but which (once properly asped) should be decisive against the present eference for uniformity above almost all other nsiderations. The mechanism of negotiating achinery between employers and employed depends a system by which the staff side levers the rates from one point to another. It first establishes at in such and such circumstances a specified rate n be justified, and then, relying on the principle of uality for all, gets this rate made universal. The oper counter to these tactics is pretty well understood in the industrial world; it is prompt concession that such and such a job does require special consideration, coupled with a detailed refusal to admit that the change must be made universal (anticipation of a legitimate demand before it becomes a grievance is, of course, one better). In the hospital world this should often mean a rate for a particular hospital—for example on account of the locality. The conduct of the employers' side of negotiations of this kind is a highly skilled matter, and we suspect that in the hospital world the technique is much better understood by the staff side than by the miscellaneous groups that represent the Minister and the taxpayer. (Has the Minister on his staff a really expert negotiator fully versed in these matters? We do not know.) The point here is that from the angle of the Minister, anxious to preserve due economy in the administration of the hospital services, the condition that no hospital ought to be allowed to pay more than the scheduled rate is not intelligent; it is a blunder, as a mere matter of tactics. It is playing into the hands of the other side: it stands therefore doubly condemned—a handicap to the efficiency of the hospital service, and a handy weapon with which to beat the Government. The situation now arising is a challenge to the authorities, and the reputation of the Minister and his advisers will suffer unless steps are promptly taken to meet it. It is not sufficient that they should say "it is a question for the negotiating machinery we have set up," for it is the terms of reference of the negotiating committees that need to be looked at. Enough damage has been done in the nursing world alone by the failure to think clearly on these subjects, and the hospital service is bound to be impaired until the matter has been threshed out.

What then should be done? We would not suggest that we could forthwith revert to the old system whereby each hospital authority settled these matters for itself. Freedom for the hospital to spend a round-sum "budget" is, it is true, a highly desirable objective; but as things stand today it would be idle to press this plan so far as to claim freedom for each hospital management committee to settle salaries and wages entirely regardless of what is being done elsewhere. Some central machinery seems to be inevitable; but it must be tempered with real discretionary power to the people on the spot. A formula—or rather a series of formulæ—must be found to give the hospital management committees some authority to exceed the Whitley Council rates whenever it is really necessary. For example, it might be provided that as regards caterers, cooks, domestics, and other groups where the hospital is in direct competition with non-hospital employers, the hospital management committee might be given authority to exceed the specified rates by as much as 50% provided that the total amount so expended in any one year did not exceed such and such a percentage of the total budget of the management committee. Where such arrangements had to be made permanent the approval of the regional board might be required. In dealing with doctors, nurses, and medical auxiliaries it might be desirable to proceed on different lines—i.e., by the method of a regional (or national) fund analogous to that being evolved to induce the general practitioner to work in the less attractive areas.

Our immediate criticism is not so much of the attempt to exercise some central control as of the crudity in the present arrangements with their reliance on the simple rule of uniformity. The hospital services are vast and complex, and the complexity will have to be matched in the arrangements made. If you have an extensive railway system it is necessary to have a Bradshaw, and the Bradshaw must take account of the gradients of every little branch line. It is no use to say "we shall assume that all trains run at the same speed everywhere." It is no use to say "we shall leave it to each little line to settle matters for itself." Nor, where hospitals are concerned, is it wise to say "we shall assume that everything that is called a hospital is equal to everything else that is called a hospital, and anyone working in one hospital must be paid just the same as someone working in another"—just because they happen to be graded to fall into the same categories in discussions which set out to discover minima for the various groups.

Small-gut Obstruction

OBSTRUCTION of the small intestine is of three main types, which may to some extent overlap. It may be an ileus, where the fault lies in the propulsive mechanism of the gut and no organic obstruction is present; it may be an occlusion of the lumen of the bowel; or it may be a strangulation, when cessation of the blood-supply to a segment of the bowel overshadows in importance the probable concomitant occlusion of the lumen. The distinction between these three main classes of obstruction has become of cardinal importance in the past few years because continuous gastro-intestinal suction has been shown to be astonishingly successful in the right type of case but dangerous in the wrong type. In ileus gastro-intestinal suction is the correct and usually the only treatment needed—it goes almost without saying *that the water and chlorides removed must be replaced* intravenously. In occlusion of the bowel lumen suction is a valuable and often life-saving part of the preparation for operation; it may be prolonged and occasionally may by itself relieve the occlusion. But in strangulation suction is a highly dangerous form of treatment if prolonged for more than the time needed to empty the upper reaches of the alimentary tract and so prevent the patient drowning in his vomit during induction of the anæsthetic. In strangulation no amount of suction can prevent organisms and plasma escaping through a dying bowel wall, or stop arterial blood being pumped into a capillary bed from which there is no venous return. The sooner this migration of the right things to the wrong places is checked by operation the better the patient's chances. AIRD,[1] who has so lucidly interpreted for surgeons the original work of himself and others, has said: "In some quarters the introduction of suction drainage has given a fall in the fatality-rate of occlusion but a rise in that of strangulation, operation in the latter condition being sometimes dangerously delayed by failure to distinguish it from occlusion."

The principles of treatment for small-bowel obstructions are easy to understand. Apart from ileus, whose cause and presence are usually obvious, the main difficulty lies in diagnosis. It is curious t modern advances in the treatment of occ and strangulation—suction drainage, antibiotic intravenous therapy—are directed to over the late features of the obstruction. There is n for them in the great majority of early occl and strangulations. *Early diagnosis permits sa* speedy surgery on a patient whose physiol still nearly normal. It is failure on the part eit the patient to summon medical aid or of the to achieve a diagnosis that provides the c which the correct use of modern aids make difference between life and death. The pati often responsible for delay, but doctors still times miss strangulated inguinal hernias becaus have not looked for them, or, with more e internal obstructions because they could fe lumps. To watch a patient with severe colick in the abdomen and vomiting until he show tension, dehydration, shock, *and signs of inf is to wait dangerously long. Any patient in* the symptoms give reasonable ground for susp obstruction needs to be in hospital. There, d can often be dispelled by a plain X-ray film abdomen to reveal distended coils of bowel are not clinically obvious.

The patient reaching hospital with a late obstru offers a pretty problem to the surgeon if the ca not clear. If there is a tender irreducible hern is reasonably plain sailing. But if the only abn physical sign is a distended abdomen it is diffic know whether to wait, so that suction and venous medication can make the patient with a occlusion safe for surgery, or whether to op at once and not prejudice the chances of a p with an internal strangulation. Two point of some help in these circumstances. Loc tenderness in the abdomen, with rebound tende indicates infection and therefore strangulation; abdominal pain continuing after an hour or tw gastro-intestinal suction shows that the pain is no to colicky contractions of the intestine but to s thing else—probably a strangulation. COLLER BUXTON,[2] in reviewing 198 small-bowel obstructi contend that even in occlusion operation is indica as soon as possible. They record three cases in wh suction drainage relieved the symptoms but bowel perforated at the site of an occluding carcin Their success-rate of 68% in attempts to get a M Abbott tube past the pylorus will be envied by t who have often had to be content with gastric suc because a long tube could not be induced to further. They found that peritonitis was the monest cause of death, and they emphasise a that early diagnosis is the key to lowered morta

Megakaryocytes and Platelets

IN the early days of hæmatology almost e blood-cell was proposed by someone as the mo cell of the platelets. In 1906 J. H. WRIGHT conten that blood-platelets are formed from the cytopl of megakaryocytes, the giant granular cells of bone-marrow; he suggested that these cells p *pseudopodia into the lumen* of blood-vessels, when the pseudopodia break off the fragments f elets. This theory has since held the field against attacks and has recently been confirmed again Saltzman [1] in Sweden and Schwarz [2] in America. Jsing the dark-ground illumination techniques lied by Wallgren to the study of cytoplasmic icture, Saltzman found that the cytoplasm of gakaryocytes and the blood-platelets share some tures of arrangement that are found only in these s, and there are many other points of similarity t occur in few other bone-marrow and blood cells. signs of life were recognised in the platelets; odd protrusions and blisters with granules in wnian movement appear to be quite unchanged the addition of potassium cyanide to the preparans. Schwarz has studied the formation of granules megakaryocytes. The typical megakaryocyte of ne-marrow, with a uniformly granular cytoplasm, ginates from a smaller megakaryoblast that has n-granular cytoplasm. In the megakaryoblast and next stage—the promegakaryocyte—a relatively le zone appears in the cytoplasm next to the lentation in the nucleus; it is within this area at the granules first appear. Schwarz calls this le zone the "functional area," and, by studying any preparations from suitable bone-marrows, he s found that as the megakaryocyte develops this nctional area stains pinkish and the granules become ue: the area spreads as the cell develops until entually it occupies the whole cytoplasm except r a narrow peripheral rim. De la Fuente [3] scribed a similar development, but he thought at granule formation began in several areas simulneously. When the megakaryocyte divides, the nctional area is not involved and remains unaltered size and shape; the nucleus appears to take no rt in granule formation. The megakaryocyte, hwarz points out, thus behaves like any other ll whose cytoplasm develops a "specific functional ansformation." It is only when the cytoplasm is lly granular that platelets are formed, by the eaking up of pseudopodia. Schwarz also discusses e appearances of the megakaryocyte in thrombotopenic purpura, which is well known as a primary sease and also occurs as part of other syndromes ch as aplastic anæmia. Splenectomy is effective eatment for most, though not all, of the primary ses but is useless in the secondary type. Since ie blood-platelets are so much reduced in this form purpura the megakaryocytes have naturally been refully studied in the hope of finding a clue to the tiology of the disease and explaining the occasional ilures of splenectomy. Schwarz finds that the egakaryocytes usually look quite normal; granule rmation in the cytoplasm proceeds in the way scribed above. There is often hyperplasia of the egakaryocytes, and—exactly as with hyperplasia of ther types of marrow cells—early forms are relatively creased. On the other hand, cases have been ported in which the megakaryocytes were reduced r even absent. In another group distinctly abnormal egakaryocytes have been found; a recent example the description by Dameshek and Miller [4] of odd egakaryocytes with non-granular cytoplasm that they call "lymphoid forms." Differences of technique make comparison between different reporters difficult, but deficient granule formation is common to all. Schwarz examined the marrow from 26 patients with primary thrombocytopenic purpura and found deficient granule formation in only a single case. The early megakaryocytes of this patient had a "functional area" that appeared and enlarged as in normal cells, but no granules developed in the area.

There thus seem to be three types of primary thrombocytopenic purpura: (1) the common type with normal megakaryocytes, (2) a type in which granule formation fails, and (3) one in which the megakaryocytes are degenerate or show cytotoxic changes. The second type, in particular, has had undue publicity, but Schwarz's estimate that only about 4% of patients show abnormal marrow pictures will surely be supported by anyone with experience in this difficult field. Consequently statements that splenectomy in thrombocytopenic purpura should only be recommended if a characteristic marrow picture is found [5] are premature. The knowledge that the clinical syndrome of thrombocytopenic purpura has a varied marrow picture may enable us to sort out those whom splenectomy is less likely to benefit, but the evidence has yet to be produced.

Annotations

ROYAL MEDICAL BENEVOLENT FUND

> "Letters of inquiry from medical men which reach the office from time to time lead the Committee to conclude that deserving cases fully entitled to relief fail to be directed to the Fund."

Mr. R. M. Handfield-Jones,[6] chairman of the committee of management of the Royal Medical Benevolent Fund, reports that in spite of the efforts of the central office and the local secretaries, the ladies' guild, and the British Medical Association, many doctors are still unaware of the work and scope of the Fund. How wide this scope is may be judged from the Fund's "proud tradition for a great many years that no applicant, medical man or woman, wife, widow, or child, is refused assistance if the need is real." Moreover, it is not only subscribers, or the relatives of subscribers, who are entitled to apply for help: the Fund is ready to help the whole profession. At the case-committee meetings none of the members knows whether the applicant has been a subscriber or not. Those who have contributed regularly to the Fund realise this already; but in order to explain the work of the Fund to the profession at large the annual report is this year being sent to every doctor in England, Scotland, and Wales. Since the little booklet is filled mainly with accounts, it does not take five minutes to glance through the four pages allotted to Mr. Handfield-Jones. The information he packs into them has a personal interest for us all, since as he says "an honourable and learned profession should be able to cope with its own casualties." He foresees many years of necessary work for the Fund, despite national insurance: for even the most benevolent of national schemes cannot take account of all the ills that flesh is heir to, all the disasters which may overtake a doctor's family when he is disabled or struck down. Mr. Handfield-Jones quotes two cases characteristic of those which came before the Fund: an aged doctor, infirm with failing vision, is trying to carry on practice to support an invalid wife;

a man under fifty with malignant hypertension, whose wife must stay at home to nurse him, has three children who need help to complete their education.

In such circumstances as these, grants are vain unless they are generous, and therefore the Fund has need of more than all the money it raises. In the last thirteen years subscriptions have increased from £13,500 yearly to £23,900—an increase of more than £10,000 yearly over a period which includes the second world war. Last year the Fund's income was £36,968; and £32,000 of this went out to relieve poverty and distress. Some, moreover, went to maintain Westmoreland Lodge, the residential home at Wimbledon now happily occupied by twelve elderly ladies, beneficiaries of the Fund, who had been living lonely and straitened lives in single rooms. Over £2300 was distributed in Christmas gifts to the fund's beneficiaries.

No appeal for funds has ever been made to the general public: this is our own responsibility and one which the profession as a whole can well carry. It is surely right that such an intimate and benevolent undertaking should, as the report says, claim the interest of every member of our profession.

POSTERIOR CULDOSCOPY

In the United States some gynæcologists are using endoscopy of the pouch of Douglas through the posterior fornix as an alternative to exploratory laparotomy, and the bastard French-Greek term "culdoscopy" has been applied to this procedure. Abdominal peritoneoscopy has never caught on widely here, though it is nearly forty years since it was first thought of, but this approach through the posterior fornix is said to avoid the undesirable features of abdominal puncture. Decker[1] gives a detailed description of the technique. The patient must be examined in the knee-chest position or the view will be obscured by coils of intestine. Unfortunately, this is the most disconcerting of all positions for the unanæsthetised patient. With the help of procaine local anæsthesia the trocar is inserted through the posterior fornix, and a pneumoperitoneum results at once if the pouch of Douglas has been successfully perforated. Either carbon dioxide or air can thus be admitted and the intestines tend to fall out of the way. The electrically lit culdoscope is then inserted and the pelvic cavity visually explored. Decker describes his experiences in 77 cases selected because of difficulty in diagnosis, and Te Linde and Rutledge[2] give a similar series of 56 cases. In about 10% of the patients the operation failed, either because of a loosely attached peritoneum which "rides ahead of the trocar" or because of a pelvic mass or adhesions. Neither series was marred by visceral injury, hæmorrhage, or peritonitis.

The cases for which this investigation is regarded as suitable are the differential diagnostic problems of ectopic pregnancy, pelvic inflammatory diseases, acute and "chronic" appendicitis, pelvic tuberculosis, and endometriosis, and for assessing the state of the pelvic organs in sterility. The claims are too sweeping to be ignored, but it is doubtful whether this procedure will be used much in this country. With accurate clinical examination and the accessory laboratory aids, such as leucocyte-counts and endometrial biopsy, the proportion of cases in which culdoscopy might be useful should be small. Then, it is in just the cases which often invite visual inspection of the pelvic organs—e.g., cases of chronic pelvic pain with a tender fixed retroversion or an indefinite tender mass—that the risks of such an inspection from perforating adherent intestine would seem to outweigh its possible advantages; moreover, in these cases the field would sometimes be obscured by adhesions, pus, or tarry blood. Of all the forms of gynæcological examination, this must be among the rigorous from the patient's point of view—its use cases of sterility may lead the cynic to wonder w next these unfortunate women will have to endure in next hundred years. Nevertheless, when he the frequency of errors in clinical diagnosis, the of unnecessary laparotomies done, and the temptatio radical surgery which abdominal exposure of pelvic viscera presents, even the most conservat gynæcologist will acknowledge that culdoscopy attractions.

HOUSEWIFE'S LOAD

The housewife is the freelance of the labour mark and the diagnostic sign of a freelance is that he is n free. The job which can be done "in any odd is at the mercy of anyone who cares to interrupt and everybody borrows time from the one member the family whose time is not sold in neat sections, down with a whistle at either end. Last year Dr. Instone[1] made a study of 61 Sussex housewives, found that their state of health was not good for the lives they had to lead. They were nearly tired, many had varicose veins and postural defe some had bad teeth or bad feet, some were stout hypertensive. Their fatigue, she thought, was not lack of sleep, but rather to much standing in and basket-carrying, and to faulty feeding (many them making a practice of giving up their protein other members of the family). Dr. Dagmar Wilso has now made two small studies, the first of Oxfordshire, Berkshire, and South Devon women, 127 them townswomen and 67 rural. Unlike Dr. she heard few complaints about shopping. Most of women were interested in cooking and satisfied their cooking arrangements. Some complained of to share their homes with additional relatives, spoke more approvingly of lodgers, who contrib to expenses without being so much of a strain on temper. More than half of them were married to workers, nearly a third to unskilled workers, and t remaining 4·3% to professional workers. Over quarters reported some sort of strain or stress— crowding, deficient water-supply, and loneliness whe children had left home being among these. Only 7 were under medical care, but physical suggested that a further 31% needed medical or treatment. In addition, over three-quarters had foo troubles such as flat-feet, corns, or bunions, and 12% had varicose veins.

The second survey was made on a group of 57 women between the ages of forty and sixty who had lived for nearly three years on "an estate of 250 houses situated on a sandy hilltop near the city boundary and circum scribed by fields and gardens." She found 20 of them good health; the rest complained of such things menopausal symptoms, gynæcological disorders, tory and gastro-intestinal ailments, nervousness, diseases of the bones and legs. Only 3 of this had foot troubles; 1 had severe varicose veins; 5 simple goitre and 1 was myxœdematous. Only 2 under a doctor's care at the time of the inquiry, was felt that a further 11 should be having me advice. In this group nearly a quarter were the of professional workers, and nearly two-thirds wives skilled workers; only about a tenth were married unskilled workers. There was only 1 case of crowding. All but 6 were satisfied with their arrangements, and their food was probably in caloric value, though they complained of mono and here again a large proportion of them gave up or part of their protein ration to other members of family. Unlike the first group they suffered little

tress. Dr. Wilson concludes that fatigue and foot ble are—as might be expected—partly the outcome cial factors. It is surely noteworthy and unexpected, ever, that in the first group the main leisure activity reading; in the second, more surburban, group the interests were radio, reading, or the cinema. In groups there were women who enjoyed communal ities, such as those of the women's institutes.

ese findings, suggestive rather than striking, might be followed up by wider surveys. There seems to ood evidence that housewives neglect their ailments, o some of their protein ration, and suffer—anyhow he lower income-groups—from undue fatigue. It ot be that in every case they do these things because, he men say when ringing pigs, they like it.

SYNCHROTRON AT THE ROYAL CANCER HOSPITAL

HE synchrotron, or to give it its correct name the -synchrotron, which has now been installed in the ical physics department of the Royal Cancer Hospital, inspected by senior officials from the Ministry of lth and others on July 5. With this device electrons be accelerated to extremely high energies and can efore be used as a source of very penetrating X iation. The electrons are accelerated, not by allowing n to move between electrodes across which a high-age difference is maintained, as with the usual ay equipment, but by the action of a changing netic field together with a special type of radio-uency oscillator. A beam of electrons is emitted n an "electron gun" inside an evacuated glass vessel between the poles of a large electro-magnet. Under action of the magnetic field the beam of electrons es in a circular orbit in the glass vessel, and as the gnetic field is increased and the radio-frequency llator brought into action the electrons are accelerated their orbit. By careful design of the apparatus the trons may be made to move round the same circular it with increasing energy until they strike a target so produce X rays. An X-ray tube running at million volts would be required in order to produce rays of the same penetration as those produced by s synchrotron.

n the last few years it has become clear that progress the radiation treatment of deep-seated cancer depends being able to apply radiations of greater penetrating wer. When the first betatron was described by Kerst the United States, it was realised that this instrument d great promise in the treatment of deep-seated cer, but that much work must be done before it ld be used with safety and precision. Now, for the st time, a synchrotron has been introduced into a spital for full-time use. The apparatus installed at Royal Cancer Hospital is the first of two developed this country for the Medical Research Council, which s borne the cost; the second is now being installed in department of radiotherapeutics at the University Cambridge. The research work on these instruments s been done largely at the Telecommunications search Establishment, Great Malvern, which is now rt of the Atomic Energy Research Establishment; magnets and much of the electrical apparatus have en built by the English Electric Company, Stafford.

The synchrotron at the Royal Cancer Hospital is used in a basement laboratory which is partly under-ound, so a large measure of very efficient natural otection is provided against the penetrating radiation. e magnet assembly from which the beam of X rays l emerge is reasonably small, being a cylinder 4 ft. in ameter and 4 ft. high; but there is a considerable ount of ancillary apparatus which is housed a short stance away. Protection of personnel is one of the ain problems; and members of the hospital's physics aff have studied the subject on betatrons and similar devices in America. Concrete bricks in walls 3 ft. thick have been used as the main protection for the operator's room. Before the instrument can be used for clinical work, much physicial and biological investigation has to be done with a view to measuring dosage and the distribution of the dose in the body. Owing to the particular characteristics of this very high energy radiation it will be possible, using a single field, to give a dose several centimetres under the skin several times as great as that received by the skin, so skin tolerance should no longer be a limiting factor in the treatment of deep-seated neoplasms. Clearly, however, it will be necessary first to learn precisely the distribution of dose in a medium similar to the body, since otherwise great damage might unwittingly be done in clinical use.

The synchrotron provides no fundamentally new method of treatment, but it is a technical development that promises help in one of the most baffling conditions with which medical science has to deal.

NERVE-ENDINGS OF THE NIPPLE

THE nipple, like a one-note man in an orchestra, appears unobtrusively, gets ready, and, having only a small part to play, is hardly recognised to have a part at all. Nevertheless, the nipple is more than a passive connecting link. It is an organ with positive physiological activity peculiar to itself. Cathcart and his colleagues[1] in Glasgow have stimulated thought on the subject by describing nerve structures in the nipple and drawing attention to its profuse innervation, both somatic and sympathetic. The nerve-endings which they have demonstrated by modern methods of staining conform in the main to the perceived sensory responses of the nipple. The foremost of these, pain, is presumably transmitted by the free endings which abound. Light touch is not felt on the surface and no nerve-endings were found of the types shown by Woollard and his co-workers to be concerned in its perception. More than a light touch on the nipple is recognised either by the deeper layers or by structures deep to the nipple. It is not surprising therefore that lamellated corpuscles of the Pacini type were only found behind the nipple. Heat and cold are keenly felt by the nipple; Krause end-bulbs were seen in it but no clearly recognised Ruffini endings to register warmth.

There must also be sensory responses peculiar to the nipple or to its adjacent tissues, though they are not clearly felt in consciousness. Their anatomical basis is still elusive and their separate existences uncertain. Among these is the one evoking posterior pituitary secretion, which leads in the full breast to the process recognised as the draught. The sensory receptors for this are thought to lie in or behind the nipple rather than within the mammary gland proper. Stimulation of the nipple itself or of the skin very near to it is apparently the specific stimulus here, though secondarily the reflex can become conditioned to many stimuli. Then there is the response to touch in the neighbourhood of the nipple which produces contraction of smooth muscle beneath the areola. This in turn makes the nipple stand out and the areola pucker. Although one may latinise the description and speak of erection of the nipple the word gives a false idea of the process, which is akin to that which makes goose flesh and does not appear to be vascular in nature. The contraction of the areolar muscle makes a knob of a flaccid nipple so that on contact the baby's cheek feels the nipple. It also provides a device like a cherry on the end of a wide soft stalk which the baby's mouth can draw in. Next there must be some nervous response to suckling which maintains the secretion of milk, for in animals secretion fails after denervation unless maintained by suckling at another intact nipple. Despite the traditional

1. Cathcart, E. P., Gairns, F. W., Garven, H. S. D. *Trans. roy. Soc. Edinb.* 1948, 61, 699.

view it probably does not arise from the fullness or emptiness of the mammary gland. How far this process which calls out the formation of milk is linked with the posterior-pituitary evoking one is unknown.

There is some evidence of sphincter action within the human nipple and sphincteric tissue has been described there. Now Cathcart et al. report finding a new type of neurofibrillar network, with an outline suggesting an oak leaf, ending in it. A comprehensive account of the histology of the nipple, which these workers hope soon to give, should add considerably to our knowledge of the responses to stimulation of the nipple, but it is essential that structural work of this kind should be correlated wherever possible with function.

THE N.H.S.

For inquirers at home and abroad the Ministry of Health and the Central Office of Information have produced a brief and readable account of the National Health Service.[1] This points out that the N.H.S. and the related social interprises require "large resources which can be made available only by the determined efforts of a people paying its way by its work"; but it argues that, considering everything, the service has at least been launched with remarkable smoothness.

> "All big social changes start with a certain amount of uncertainty, until people get used to the new way of doing things; and this Service cannot be comprehensive in the fullest sense until the country is farther along the road to prosperity and a rising standard of life. The public has still to learn how to use the new facilities properly and economically; and those who are actually running the Service have to get used to new conditions and changing needs. But if the various professions really join forces with the laymen in the organisation described in this booklet, they can carry out a progressive new deal in medical care which will redound to the benefit of all."

As might be expected, much is made of the need to change a state of affairs in which the hospitals were owned by "some 2000 separate, and often jealous and conflicting, local public or voluntary authorities": "new forms of organisation were required to rescue the health of the people from what Lord Horder called 'the maze, the unwieldiness, the overlap, the uneconomy, the lack of integration of our health services.'" On the other hand, it is recognised that it would be wrong for medical needs to be met everywhere in the same way: "medicine thrives on experiment and comparison of different ways of doing things; uniformity of method or belief is its enemy." Those who hold that too much attention is being paid to curative medicine may get some comfort from reading that the present expenditure on the N.H.S. (which amounts to about 2*s.* 6*d.* per head per week) "can be justified only on the basis that the essential aim of the Service, and all who work in it, must be to *prevent* illness." Similarly, proper emphasis is laid on medical care in the home as contrasted with care in hospital: the pamphlet says that "for nearly everybody the family doctor is the pivot of the whole scheme apart from dental treatment," and describes how fuller use of the home (or district) nurse, of home-help services, and of sickroom equipment provided by local authorities will prevent unnecessary admissions to hospital.

At a time when capital expenditure must be kept to a minimum, and only the most urgent schemes for the extension or repair of hospitals can be permitted, the building of comprehensive health centres "on any scale" is considered impossible. We are also told once again that "more study is also needed of the kinds of centres most worth trying out before any large-scale experiments are launched." However, it is encouraging to hear that "the building and testing of health centres in action, in different forms and circumstances, in large towns and small, in suburbs and country areas, is a task for the next few years." This leads up to the st understatement that "during that time a great perhaps most, family doctors will continue to p outside health centres." Similarly irritating i remark that in the old days "the family doctor, w single-handed or in a small partnership, usually h much to do because he had too many patients, insuf help, and insufficient equipment, and he was except with great difficulty to keep up to date or to reasonable leisure." Little attempt is made to e how the coming of the N.H.S. has improved the ditions for general practice or arrested their deterior

The pamphlet does not go far below the surface the light in which it describes the N.H.S. is nat rosy. Nevertheless, like the Ministry, we hope t will be read by "those who are workers in the Se without whose understanding and whole-hearted ef cannot succeed." Any description of the service brings us back to its main objects is useful at the p time, reminding us that more is at stake than of service.

A FIVE-YEAR PLAN

Six years ago Lord Nuffield endowed the Nu Foundation with £10 million and urged them to g with the job of promoting the health and well-bei mankind. The first year was spent quietly m plans, and by the end of their first active quinquen from their total income of £2³/₄ million the found have given away £2¹/₄ million in grants. To give use is a responsible and exacting task, but the found have known how to be at once discriminating and and their grants range from £100,000 for the Unive of London's chair of child health to £1500 to enabl Medical Research Society to purchase *Clinical Scien* memory of Sir Thomas Lewis.

In their fourth report[1] the foundation, besides gi an account of their stewardship, also deal with plans for the future. In continuing to further the he and well-being of mankind they hope to help in discovery of new knowledge especially in biology social studies—sciences which they feel have been la somewhat overshadowed by the more fashionable ph and economics. They are also anxious to encourage application of existing knowledge to everyday t especially by joint effort among groups of expe Through the National Corporation for the Care of People the foundation look forward to continuing th work on behalf of the old, especially the arrangem for the care of the semi-sick who at present tend to neglected because of the gap between the hospi authorities and the local authorities. From their ow resources and as trustees of the Oliver Bird Fund th will also continue to support research into chro rheumatism.

In the last twenty years research has become incre ingly expensive. Today the man in the small s private laboratory is at best grievously handicap To achieve his utmost he may need access to facil which can only be provided by the Government, a uni sity, or a large commercial firm. But this does mean that the private patron should go out of busin As the foundation point out, he has the urgent task seeing that "creative minorities" get a first hea and a chance of wider support. In their budget the next five years the foundation have therefore o more made provisions for fellowships and training gr which will help the unique individual and pro to get their chance.

Prof. **Hilda Lloyd** has been elected president of Royal College of Obstetricians and Gynæcologists succession to Sir William Gilliatt. She will ass office in October.

INTERNATIONAL CONGRESS OF OTOLARYNGOLOGY

JRING the week beginning on Monday, July 18, 1300 delegates, from forty nations, attended this erence in weather which gave them the opportunity eing London at its best. The delegates agreed that meeting—the first since the war and the fourth the original congress in 1928—proved to be the best nised and the most generally successful of the series. ceremonies and discussions were held at King's ege in the Strand, and it was clear to each delegate oon as he entered the college to register that his rtainment, his accommodation, and the conduct of multitudinous items of the congress had been carefully ned. Mr. F. C. W. Capps, the general secretary, been engaged on the detailed plans for two years, the experienced help of the secretariat of the Royal ege of Surgeons. Mr. W. A. Mill was financial etary, Mr. G. H. Bateman academic secretary, F. C. Ormerod and Mr. C. P. Wilson scientific etaries, and Mr. Myles L. Formby reception secretary. chairman of the ladies' committee was Mrs. V. E. gus. The president, Mr. V. E. Negus, infused a py spirit of international friendliness into the ceedings.

he great hall of King's College was crowded when the chess of Kent arrived to declare the congress open. hoped that it would prove important not only as orum for the exchange of medical ideas but also as means of furthering international understanding. f. F. R. Nager, speaking for the visitors from overs, expressed the gratitude which they all felt at the d which Great Britain was giving the world in its rch for peace.

The profusion of the fare provided made it impossible the delegates to attend every session. They were nstantly faced with the need to decide where they uld spend any given moment—for instance, there were erally no fewer than four academic sessions in progress one time, and beyond these there were the attractions demonstrations, films, exhibitions, visits to hospitals, d sight-seeing tours.

Exhibitions of surgical instruments, of hearing-aids, medical books, and to illustrate the history of otoyngology were well patronised. Despite the journey the fourth floor that it entailed, the collection of atomical and pathological specimens attracted many sitors. On this floor too were to be seen Dr. Gray's markable specimens illustrating the anatomy of the ner ear, and Mr. Negus's unique collection of ecimens demonstrating the comparative anatomy of e larynx.

The exhibitions of medical films were particularly pular, perhaps not only because of their individual cellence but also because they circumvented the curse Babel. If "The function of the ear in health and sease," produced by Dr. H. G. Kobrak, of Chicago, d the "Slow motion film of movements of vocal cords" oduced by the Edison Bell Co. are representative of e general level of achievement, one can say that the edical film is among the most noteworthy of the cent advances in medical teaching.

Some idea of the lavish social programme may be thered from the following diary: *Monday,* President's eception in the Gardens of the Zoological Society London. *Tuesday,* banquet at the Dorchester otel. *Wednesday,* reception by His Majesty's overnment. *Thursday,* receptions by the London ounty Council and at the Royal Society of Medicine. *riday,* reception at the Royal College of Surgeons of ngland.

ANTIBIOTICS AND CHEMOTHERAPY IN SINUSITIS

The proceedings began with a film made by Dr. Paul Hollinger (Chicago) illustrating his technique of motion photography in colour of the structures of the ear, nose, and throat in health and disease. The perfection of the photography was new to many of the European delegates.

After lunch the academic programme began in earnest, with papers by two British pioneers in the study of antibacterial drugs. Sir Alexander Fleming, F.R.S., gave an account of the ways in which the blood-level of penicillin could be maintained throughout the twenty-four hours. He referred to the more recent antibiotics —streptomycin, aureomycin, and chloromycetin—and to the effects which might be expected from a mixture of these substances. The organisms causing sinusitis were much the same as those responsible for other respiratory infections, and we had antibiotics to deal with all of them; the problem was to get the drug to the seat of the infection.

Sir Lionel Whitby asked: "Have the sulphonamide drugs any place in treatment now that we are armed with antibiotics?" His answer was "Yes," first on the score of their availability and secondly because of their action on the gram-negative bacteria. He indicated the conditions under which these drugs could be expected to exert their maximum effect, and stressed the importance, in otolaryngology, of free drainage of secretions.

Prof. Carlos Larroudé (Lisbon) also emphasised the need for drainage of pus whenever it was present. The real value of these therapeutic agents lay in the treatment of acute rather than chronic disease. The symptoms of acute sinusitis and its complications were greatly modified where these drugs were used, and this opened up a new field for clinical study.

Subsequent speakers amplified Sir Alexander Fleming's remarks on the uselessness of administering penicillin if local factors were preventing its concentration at the site of the disease. Prof. J. J. Barroilhet (Santiago) felt that this was never achieved by the use of aerosols, and Mr. E. G. Collins described his experience with indwelling ureteric catheters as a means of applying penicillin to the maxillary antra of children for the relief of subacute antritis.

Two points stand out from this afternoon's proceedings: (1) penicillin and other antibacterial drugs do not replace, but are a valuable adjunct to, surgery in the treatment of nasal sinusitis and its complications; and (2) these drugs are useless unless they reach the infected tissue in sufficient concentration.

AURAL VERTIGO

Prof. F. R. Nager (Zürich), in opening this session, dealt principally with the question whether labyrinthine hydrops in the absence of inflammation could be regarded as the fundamental lesion in Ménière's disease. He showed some beautiful microscopical sections through the labyrinth from a variety of sources, illustrating the frequency with which these findings were present. In his opinion in two-thirds of all cases of Ménière's disease a non-inflammatory labyrinthine hydrops could be demonstrated.

It was a great disappointment to the several hundred delegates present that Prof. C. Nylén (Uppsala) was too ill to attend. His paper was read by Dr. G. Herberts (Uppsala). Over many years Professor Nylén's experience had led him to advocate conservative treatment in most cases of aural vertigo, and 70% of 180 patients recently followed up had been so treated. He considered it necessary to investigate each case carefully, to exclude a central neurological lesion. A proportion he considered to be circulatory and others allergic in origin. In suitable cases his suggested treatment included a modification of Day's operative procedure.

Dr. W. J. **McNally** (*Montreal*) reviewed a series of 200 cases, treated by him over ten years. His most important conclusion was that spontaneous remission with an average duration of four years was common in Ménière's disease. This necessitated the greatest caution in assessing results of treatment. It was not wise to speak of cure until a case had been free from symptoms for five years. Failure to appreciate this fact might lead to the most misleading interpretation of the value of this or that remedy. Like Professor Nylén he held that surgery should be reserved for the very few selected cases. He wondered if, in destroying the labyrinth, we were not sometimes interfering with Nature's danger signal.

It was clear that Dr. McNally's paper had had its effect on those who took part in the discussion. For instance, Mr. **Garnett Passe** was at pains to interpret his results after upper dorsal sympathectomy as being symptomatic improvement rather than cure.

Dr. C.-A. **Hamberger** (Stockholm) gave an account of his work on guineapigs, in which he had attempted to identify the lesion produced by streptomycin. He had found lesions both in the vestibular nuclei and in the vestibular ganglion, and he wondered if the former were secondary to the latter.

Prof. G. **Portmann** (Bordeaux) urged that a place remained for decompression of the labyrinth by removal of the saccus endolymphaticus. Mr. T. E. **Cawthorne** described the technique of his operation in which he avulses the membranous horizontal canal of the labyrinth. He also analysed his recent results.

A great impression was undoubtedly made by Dr. McNally, and the audience went away determined to be more cautious in future in the interpretation of their results.

NON-MALIGNANT STRICTURES OF THE THORACIC ŒSOPHAGUS

Dr. **Gabriel Tucker** (Philadelphia) concentrated on strictures of three ætiologies—the congenital, the short œsophagus with *intrathoracic stomach*, and the stricture following caustic burns. With the aid of an excellent colour film, he demonstrated the technique of retrograde dilatation. The patients, two of whom were children, were seen swallowing a length of string, the end of which was later recovered from the stomach through a gastrostomy by the aid of a sucker. Bougies attached to this string were then drawn up the œsophagus.

Prof. J. **Terracol** (Montpellier) described the frequency with which caustic burns of the œsophagus were encountered in France. He indicated his treatment, which appeared to agree with *that of the previous* speaker.

Dr. P. G. **Gerlings** (Amsterdam) also remarked on the common occurrence of caustic burns, which had become increasingly frequent during the war. He stressed the vital importance of skill and judgment born of long experience in the treatment of these cases, and advocated transthoracic resection of the stricture where bouginage is impracticable. Speaking of the treatment of short œsophagus and associated stricture, he dwelt on the insufficiency of the cardiac valve and the regurgitation of gastric juices as ætiological factors.

The **President** paid tribute to the hydrostatic bag as an invaluable instrument in achieving dilatation of strictures of the lower œsophagus. He pointed out that the credit for introducing this to the medical world should go to Dr. Tucker.

In the general discussion various speakers attention to the frequency of caustic burns of the phagus, which are apparently much more co abroad than in Great Britain. Dr. C. L. J (Philadelphia) referred to the legislation which had necessary in an attempt to reduce the number of due to children drinking caustics by accident. D **Holinger** (Chicago) drew attention to the in number of postoperative strictures. The more a surgery of the œsophagus, as practised today, presenting endoscopists with a new problem, annular stricture at the site of œsophagogastrostom

The consensus of opinion on the value of an in string in the treatment of severe strictures was lised by Dr. L. H. **Clerf** (Philadelphia). This and *the importance of gentleness and perseveranc* treatment were the main items which the stored in his memory.

* * *

In addition to these combined sessions, other were held throughout the week under the of the vice-presidents: Mr. **Kennedy Hunter**, G. **Ewart Martin**, Mr. W. M. **Mollison**, Mr. R. **Owen**, and Mr. A. J. M. **Wright**.

On leaving the congress, an Italian surgeon overheard to make a remark which *will serve* as epitome of the spirit which animated all the proceedi "Politicians create the barriers between nations; throws them down."

Medicine and the Law

Duration of Pregnancy

The case of the 360-day baby, if it may so be is to go to the House of Lords. The husband's was that he was serving overseas from June 17, 194 February, 1946, when he was demobilised. He leave in August, 1945, which he spent with his w A child was born in August, 1946. In the Court Appeal Lord Justice Denning observed that the dat the birth meant, in the ordinary course of events, the child was conceived in November, 1945. In opinion the suggestion that the period of gestation 360 days could be called fantastic. Once it was that the husband was not in England at the time, was an irresistible inference that the child was concei in adultery. Lord Justice Denning was prepared grant the husband a decree *nisi* in his application for divorce, but his two colleagues took a different Lord Justice Bucknill thought that the scientific eviden had better be re-examined at a new trial; there was clear scientific evidence on the point at issue. The court must balance the probabilities one against an and not regard it as a question of law. Lord Asquith concurred with Lord Justice Bucknill. *view of the want of unanimity in the Court of* leave was given for the parties to appeal to the H of Lords.

Not many days ago the Court of Appeal refused application by the husband to call fresh evidence. ground of refusal was that the *proposed* evidence perfectly well have been given at the original Now the Court of Appeal has ordered (subject, of to any review of its decision by the House of that there must be a new *trial when it will be* open the parties to call the best medical evidence *There have been, as Lord Justice Bucknill* remar cases of unsuccessful allegations of misconduct babies had been born 346 and 349 days after the opportunity for marital intercourse. Counsel for husband has argued that the courts will have to the line somewhere.

ON-MEDICAL CARE OF CHRONICALLY ILL CHILDREN IN HOSPITAL

B. W. MACLENNAN
B.Sc. Lond.

THOUGH much progress has lately been made in child ychology, there has been little attempt to apply this w knowledge to sick children in hospital, apart from e important work of Spence (1947), in Newcastle, and some workers in America (Gorniak 1941, Bettelheim d Sylvester 1947, Sutton 1947, Benjamin and eatherly 1947, Szurek 1947, Davidoff 1948, Jensen d Comly 1948); yet nowhere is there a greater need relate modern scientific thought to routine hospital ractice.

When one considers the non-medical care of chronically l children, the problem appears to fall into two parts; rst, the discipline and organisation of the ward, and econdly, the emotional needs of the individual child.

DISCIPLINE AND ORGANISATION OF THE WARD

If one examines the layout and organisation of the ormal hospital ward, one can understand how its iscipline often tends to become authoritarian and rbitrary. Both the size and shape of the ward may ead to this situation. Most wards are long and narrow, shape which makes it difficult to see what is going n at the far end and therefore complicates control. he number of beds is also important—20 to 25 children s far too many for easy control; 11 is probably the ideal umber for chronically ill children, and there should ertainly never be more than 15 in a ward. There hould also, of course, be one or two single and wo-bedded rooms.

The doctor's work, unless he takes particular care, laces him on a superior level to the rest of the staff nd makes him seem rather an unapproachable person o the small child in bed. As a general rule, his ward ounds are an awesome ritual, while even his most ursory examinations are undertaken in a strictly nforced silence.

Although the sister often makes a great effort to take he place of the mother with the child, she is generally oo busy to have frequent contact with individual atients and is forced to multiply regulations in order o get through the work. Also, owing to the traditional raining of nurses, undue emphasis is commonly laid on uiet, order, and cleanliness, while, in the achievement of these, it is forgotten that the patient is an actual person and not a mere adjunct to the hospital bed.

This attitude is often reinforced by that of the matron, who also insists on perfectly tidy beds, spotless lockers, and a respectful silence on her appearance. To quote an example:

> A sister had been planning an Easter treat for the ward, but the matron decided that this would be a good opportunity to take an inventory of ward equipment, and all other plans had to be laid aside.

The effect of this attitude is twofold. First, it thwarts the natural instincts of the child to be noisy, untidy, and dirty. If carried far enough, it will lead either to extreme submissiveness or to submissiveness alternating with periods of uncontrollable wildness. Secondly, it tends to harass the rest of the nursing staff, who are no longer able to be kind and affectionate to their charges but are overoccupied with routine duties.

When nurses have too much to do and too many children under their charge, they feel that their control is weak, and that they have not sufficient time to investigate any difficulties which arise. This makes discipline arbitrary. The following are examples of this:

> A few children played a practical joke on another child, with the result that there was some screaming and much laughter. The nurse-in-charge dashed up, picked out one child, and, without inquiring what had occurred, sent him off to bed. All the children felt considerable resentment, and the little boy, who was in any case rather unstable, cried for over an hour.
>
> On another occasion, two or three boys were fighting. The doctor came into the ward and deprived all the children of a treat to which they had been looking forward for some time.
>
> On a third occasion, there was to be a special supper and a show after it. The children were sitting round talking or helping to lay the supper table. The noise was not excessive, nor was there more excitement than might have been expected. The staff nurse came in and shouted that the next child to make a noise would not be allowed to go to the show. A few minutes later she came back and told one of the little girls, who was certainly not making any more noise than anyone else, to go back to bed, and decreed that the next child to talk at all would be treated in the same way. The ward was left in dismayed silence, and to a great extent the whole treat was spoiled.

Punishment is rarely necessary at all, if the nurses have the time and the knowledge to investigate the situation properly, and if they do not go in such fear of higher authority that they themselves become tyrannical.

Age-distribution is a much-discussed problem in hospitals which deal with chronically ill children. It is probably better to separate older and younger patients, both from the point of view of easy handling and because otherwise the younger tend to be too much dominated by the older children. Sometimes, too, the young children act only as satellites to the older groups, finding it difficult to make friends of their own age.

Girls and boys who have left school and started work present a special problem, for they consider themselves grown up and resent being put in a children's ward: sometimes the staff make this resentment worse by forgetting how old and responsible such patients feel, and by treating them still as children.

Many people consider it too difficult to nurse older boys and girls in the same ward, but if absolute segregation is insisted on there should be some place where children of all ages and sexes can meet in easy and natural circumstances as soon as they are able to move around. When children are in hospital for long periods it is essential not to restrict their opportunities for social experience more than is absolutely necessary.

EMOTIONAL NEEDS OF THE CHILD

In considering the second part of the problem, one must try to imagine how an ill child feels on admission to hospital. Often he has been ill for quite a long time. He has missed school and feels insecure because he is losing ground there. He is feeling very unwell, often in pain, and he knows that his parents are anxious about him and their fear is communicated to him. He is going into a strange place among strange adults and children, and he is separated, perhaps for the first time in his life, from the people he loves and from the familiar home atmosphere. He is going to live in this new environment for many months and he is worried how he will get on. The first necessity is, therefore, that he should feel that there are people round him who will love and care for him, be kind, and understand him.

It is the job of the doctors and nurses to provide the necessary medical care; it is the job of the teachers in the special hospital schools to provide for education; but the emotional needs of the child are apt to be forgotten just because they are everyone's and no-one's particular concern.

It is very important, particularly with the younger children, that they should have at least one adult with whom they can feel really secure. With the present staffing difficulties this often remains only an ideal, for even the sisters change their posts very rapidly. A possible solution would be to divide the ward into families, a doctor, a sister or staff-nurse, and one or two junior nurses being specifically allocated to each small group of children. It seems to me that the feasibility of such a procedure should be determined by experiment. However, if for administrative reasons this cannot be arranged, each child should know that there is one adult who is specially interested in him and can give him emotional security throughout the whole of his illness.

Children should not be emotionally dependent on other children who may get well and go home. There have been too many cases where a child is making slower progress than his friend. The friend goes home and the child is left lost and lonely. He begins to worry about his own condition and very soon he has a relapse. On the other hand, I know of at least one case where a child, judged as hopelessly ill, was taken in hand by a doctor, who gave him unlimited affection and constant care, with the result that, after a few weeks, the child was bouncing round the bed looking the picture of health and enjoying himself heartily. Even if such improvement were only transitory, it would surely be worth attempting.

Very ill children are now generally placed in side wards, to give them extra quiet and for the convenience of the other children. But if this is done they should not be left too much alone, for it must be remembered how anxious and insecure a very ill child feels. Wherever possible it is advisable to have a special nurse, or else the mother, attending the child.

In trying to keep the children quiet and tidy, it is often forgotten that children need to play and that they can get rid of a lot of aggression by way of constructive games. It is not uncommon in hospital to see children lying back in bed, bored and miserable, without any toys or games available. This happens particularly where the child does not make friends easily; of course the staff are too busy to spend all day amusing him, even if this were desirable. Far too little imagination is used in moving beds around until the children are next to those they particularly like. I would even move an ill-adapted child into another ward in an attempt to find someone who was congenial to him there.

Many difficulties arise because the nurses are not taught the elements of developmental psychology and have no psychologist to whom they can go for advice. It is not suggested that nurses should be trained as psychiatrists, but they should be able to distinguish the grosser forms of abnormal behaviour. For instance, such problems as violent temper tantrums and stealing are often treated as ordinary naughtiness when they really require psychiatric attention. On the other hand, behaviour which is quite normal to children at certain stages of development often becomes a major problem just because it is not recognised as such—for instance, adolescents often oppose authority merely as a matter of principle in their struggle to achieve independence. Such young people are often helped by being given some measure of self-government within the ward, and by being allowed to assist with the very young children and babies.

As the children get better, their fears and worries about going home should be discussed with them. There may be many difficulties related to physical limitations, the return to school, or even fitting back into the family. The following incident may show how such problems are sometimes expressed.

A little girl, aged 9 years, who had acquired a baby bro while in hospital, remarked, "I am not sure I want to home. I don't know if I am loved any more. Ten mo is a long time to be away." A night or two later it observed that she had started to act a play, which she originated, with one or two other friends. The plot of play was that the mother of a family, in which there a new baby boy, engaged a girl as a maid-servant; this turned out to be an infanticide and killed the baby and she was then condemned to death. This play repeated every night for about ten days, the little girl pla the rôle of the mother. When she went home, she very pleased with the baby brother, and apparently ma good adjustment.

With adolescents, the problem of future occupa crops up. Advice should be given about the choic career with particular reference to the intellige abilities, and disabilities of the individual, as wel to his particular preferences. Where necessary, the and girls should be put in touch with agencies who help to find them jobs. It is often a good thing to a few talks on careers, indicating the kind of different jobs entail, what qualities they need, what prospects there are of promotion. Most chil are very ignorant about job possibilities at the they have to make their choice.

Finally, the closest coöperation should be mainta between the medical staff and the parents. The par should be encouraged, and if necessary helped, to their children as often as possible. They should alw be given the choice of remaining with their chil when they are acutely ill, and they should always seen before the child goes home, so that they k exactly how they should treat the child and can about any problems which are worrying them.

SUMMARY

The non-medical care of chronically ill childre discussed in two parts—(1) the organisation discipline of the ward, and (2) the emotional ne of the individual child.

It is recommended that the wards for such child should be considerably reduced in size, that discip should be orientated to understanding the needs of children rather than to keeping them quiet and ti and that punishment should only be used as a resort, after any particular situation has been thoroug investigated and all other means of explanation a persuasion have failed.

Nurses engaged in caring for chronically ill childr should have the *elements of developmental psycholog* included in their training curriculum.

Sick children need the constant support of a symp thetic adult throughout the whole course of their illne and every attempt should be made to place the ch among congenial companions.

The closest possible coöperation between staff a parents is essential at all stages of the illness and recove

DISTRIBUTION OF GENERAL PRACTITIONERS

HE Medical Practices Committee has completed its ey of England and Wales and has assigned all utive-council areas or parts of them to one of schedules. two of which are given below.

chedule 1 contains the names of parts where. in the ion of the committee. more doctors are needed. Parts ed in schedule 2 are also completely open to any tor who wishes to start a practice. Admission to medical list of the executive council of places named both these schedules will be automatically granted. intending practitioners can proceed to make all ngements acting on this assumption.

chedule 3 lists areas which are "doubtful." Appliions to practise are likely to be granted, but information the hands of the committee may lead to the area ng closed. The establishment of a successful practice these areas is likely to be hazardous.

chedule 4 gives the name of the "closed areas" in ich the committee has decided that the number of tors providing general medical services is for the e being adequate. Such closure only gives the mittee the power to refuse an application to go on medical list (subject to the right of the applicant appeal to the Minister). To members of executive ncils and local medical committees, and to doctors, should convey no more than that the committee is likely to agree to an increase in the number of pracioners practising in the district and might agree with executive council to refuse to allow replacement of ractitioner who resigns. This does not mean. however. at a retiring practitioner could not be replaced. here an executive council in agreement with the local edical committee considered replacement desirable, the edical Practices Committee would agree. and, further, might suggest replacement in other instances where this peared desirable. Nor does closure mean that under other circumstances would the committee admit a actitioner to the list; personal factors advanced by e applicant, the executive council. the local medical mmittee, or others interested might cause the applicaon to be granted.

SCHEDULE 1

From the information furnished from the executive uncils. it would appear that the number of practitioners ailable in the densely populated parts of the following stricts is insufficient for local needs. For more precise tails application should be made to the local executive uncil.

COUNTIES

Bedfordshire.—Luton.

Cheshire.—Crewe and Nantwich. Hyde, Dukinfield and Stalybridge, ncorn and Stockton Heath, Newferry and Bebington.

Cumberland.—Cockermouth, Maryport.

Derbyshire.—Chesterfield B. and R.D.; Ilkeston B.: Alfreton, lsover, Claycross, Heanor, Long Eaton, Matlock, Ripley, Staveley, adlincote U.D.s; Blackwell, Clowne R.D.s.

Durham.—Felling U.D., Hebburn U.D.. Jarrow B. and Boldon D., Houghton-le-Spring, Hetton and Washington U.D.s. Chester-Street U. and R.D.. Stanley U.D.. Consett U.D. and Lanchester D., Crook and Willington U.D. and Tow Law U.D., Bishop ckland. Shildon and Spennymoor U.D.s. Easington R.D., dgefield R.D., Stockton U. and R.D.s and Billingham U.D.

Gloucester.—Kingswood.

Hampshire.—Aldershot, Eastleigh.

Hertfordshire.—Ware U.D. and Cheshunt.

Huntingdonshire.—Ramsey.

Isle of Ely.—March, Wisbech. Whittlesey.

Kent and Canterbury.—Chatham. Dartford. Erith, Gravesend, chester B.s; Crayford, Northfleet, Sittingbourne and Milton. anscombe U.D.s; Dartford R.D.

Lancashire.—Aintree, Bacup, Barrowford. Coppull. Croston, arnworth. Haydock, Heywood, Hindley. Huyton with Roby, lam. Kearsley. Leigh, Litherland. Middleton, Newton-le-Willows, escot, West Houghton. Widnes. Worsley.

Leicestershire and Rutland.—Ashby de la Zouch, Coalville, Hinck-y. Melton Mowbray (excluding Somerby).

Lincolnshire (Holland).—Spalding U. and R.D.s.

Lincolnshire (Kesteven).—Grantham.

Lincolnshire (Lindsey).—Louth.

London.—Battersea, Bethnal Green, Hammersmith B.s.

Middlesex.—Edmonton. Heston and Isleworth, Southall. Wood Green B.s; Feltham, Hayes and Harlington, Staines U.D.s.

Norfolk.—Mitford and Launditch.

Northampton.—Kettering.

Northumberland.—Ashington, Bedlington, Haltwhistle, Wallsend.

Nottingham County and City.—Arnold. Bawtry, Beeston, Carlton and Netherfield, Clipstone. Eastwood, Hucknall. Kimberley, Langold. Stapleford. Warsop, Worksop. City of Nottingham.

Soke of Peterborough.—Peterborough, Whittlesey, Market Deeping.

Somerset.—Chew Magna. Street.

Staffordshire.—Newcastle-under-Lyme B. and R.D.; Wednesbury. Bilston, Rowley Regis. Tipton B.s; Kidsgrove. Biddulph. Aldridge. Brownhills. Rugeley. Darlaston, Willenhall, Wednesfield, Sedgley. Brierley Hill. Amblecote U.D.s; Lichfield R.D.

Surrey.—Mitcham B.; Chertsey, Walton and Weybridge U.D.s.

Sussex (West).—Lancing.

Warwickshire.—Bedworth, Nuneaton. Warwick U.D.s; Atherstone R.D.

Wiltshire.—Swindon.

Worcestershire.—Bromsgrove. Halesowen, Oldbury. Stourbridge.

Yorkshire (East Riding).—Haltemprice district, Hedon district. Howden and Goole.

Yorkshire (North Riding).—Carlin How, Dormanstown, Grangetown, Guisborough.

Yorkshire (West Riding).—Castleford and Normanton U.D.s, Featherstone U.D.. Knottingley U.D., Pontefract B., Osgoldcross R.D., Horbury U.D.. Ossett B.. Wakefield R.D.. Batley B.. Heckmondwike U.D., Hoyland Nether U.D., Stocksbridge U.D., Wortley R.D.. Penistone U. and R.D.s, Hemsworth U. and R. D.s. Cudworth U.D.. Darton U.D., Royston U.D.. Darfield. Wombwell, Worsborough. Dodworth U.D.s; Swinton, Rawmarsh, Wath-on-Dearne U.D.s; Adwick-le-Street U.D., [illegible] U.D.s. Rotherham R.D., Doncaster R.D., [illegible] R.D., Conisborough, Mexborough. Dearne U.D.s; Maltby U.D., Kiveton Park R.D.

Denbighshire and Flintshire.—Buckley. Caergwrle. Connah's Quay, Hawarden. Holywell and Wrexham R.D.

Glamorganshire.—Aberdare. Bridgend. Caerphilly. Gelligaer. Llwchwr. Maesteg. Mountain Ash, Neath, Penybont, Pontypridd Port Talbot. Rhondda.

Monmouthshire and Newport.—Abercarn. Bedwas and Machen. Bedwellty, Cwmbran, Ebbw Vale, Pontypool, Risca and Tredegar.

COUNTY BOROUGHS

All of the larger cities in the country have densely populated districts, where the services of additional doctors are required. In addition more doctors are required in the following county borough areas:

Barnsley
Birkenhead
Bootle
Burton-on-Trent
Carlisle
Coventry
Derby
Dudley
East Ham
Gateshead
Great Yarmouth
Leicester
Middlesbrough
Northampton
Norwich
Rotherham
St. Helens
Smethwick
South Shields
Stoke-on-Trent
Sunderland
Tynemouth
Wakefield
Walsall
Warrington
West Bromwich
West Hartlepool
Wolverhampton

SCHEDULE 4

The committee declares the number of doctors included in medical lists and practising in the following areas to be adequate:

COUNTIES

Berkshire.—Lambourn (Hungerford R.D.), Brightwalton (Wantage U. and R.D.s).

Buckinghamshire.—Great Missenden, Prestwood, Chalfont St. Peters, Chalfont St. Giles, Gerrards Cross. Beaconsfield, Seer Green, Stokenchurch. Brill. Long Crendon. Haddenham.

Cheshire.—Hoylake and West Kirby district. Knutsford and Wilmslow (with the exception of Lymm), Bollington (Macclesfield District), Helsby (Runcorn district).

Cornwall.—St. Agnes, St. Ives and Carbis Bay, Hayle, Townshend and Fowey, Tywardreath and Marazion, Mullion, Lizard, St. Keverns, Falmouth, Perranarworthal, St. Mawes, Ruanhighlanes, Bude, Widemouth Bay, Rock, Wadebridge. Tintagel, Boscastle, St. Germans, Downderry, Millbrook, Cawsand, Upton Cross and Pensilva. Constantine, Padstow, Torpoint, Mevagissey.

Cumberland.—Alston. Bootle and Millom. Ravenglass and Gosforth. Caldbeck and Dalston, High Hesketh district, Keswick. Kirkoswald. Rowrah.

Derbyshire.—Buxton B., Bakewell U. and R.D.s, Whaleybridge U.D.

Devon and Exeter.—Yelverton, Lifton, Ottery St. Mary. Holsworthy, Lynton and Lynmouth, Pinhoe. Bradworthy, Hartland, Churchinford. Clayhidon, Culmstock. Shebbear, Beer, Seaton, Colyton, Braunton. Woolacombe, Croyde Bay. Georgeham, Ilfracombe, Shaldon, Chulmleigh, Hatherleigh, Winkleigh, Dunsford and Umberleigh, North Tawton. Sticklepath and Witheridge, Sidmouth and Sidbury. Hope Cove. Lustleigh and Bovey Tracey, Moretonhampstead. Newton Ferrers. Yealmpton. Modbury. South Brent, Buckfastleigh, Salcombe. Brixham. Paignton, Totnes, Ashburton, Kingskerswell. Teignmouth. Dawlish. Starcross. Chudleigh and Exmouth, Lympstone, Woodbury. Morchard Bishop, Charlton Fitzpaine, Bishopsteignton, Black Torrington, Bow, Brandninch. Budleigh Salterton, Tipton St. John. Chillington, Uffculme.

Dorset.—Abbotsbury and district, Bourton and Gillingham, Branksome. Broadstone. Buckland Newton and Cerne Abbas, Canford Cliffs, Charmouth and Lyme Regis, Child Okeford, Corfe Castle and district, Cranborne, Dorchester, Evershot, Ferndown, West Moors and Kinson. Handley and district, Maiden Newton, Marnhull and district. Milton Abbas, Winterbourne Stickland and districts, Puddletown. Shaftesbury and district, Stalbridge, Sturminster Newton. Swanage, Yetminster.

Durham.—Stillington.

Gloucestershire county and city.—Bishops Cleeve, Blockley, Moreton-in-Marsh, Chipping Campden, Mickleton, Charlton Kings.

Cheltenham, Cleeve Hill, Prestbury, Fairford, Lechlade, Minchinhr [illegible]

[illegible] Fleet.

[illegible] Kington, Hay-on-Wye, Staunton-on-W.

Hertfordshire.—Braughing R.D.

Huntingdonshire.—Alconbury Weston, Buckden.

Isle of Ely.—Manea.

Isles of Scilly.

Kent and Canterbury.—Lydd, Tunbridge Wells, Sandwich B.s; Broadstairs and St. Peters, Herne Bay, Sevenoaks, Southborough U.D.s; *Ashford (East), Ashford (West), Cranbrook* and Tenterden, Romney Marsh and Sevenoaks R.D.s.

Lancashire.—Allithwaite and Grange-over-Sands, Broughton West and Kirkby Ireleth, Coniston, Hambleton, Preesal, Pilling and Stalmine with Stainhall, Haverthwaite, Hawkshead, Lytham St. Annes.

Leicestershire and Rutland.—Peatling Magna, Hallaton, Somerby, Uppingham, Market Overton.

Lincolnshire (Kesteven).—Bassingham, Billinghay, Castle Bytham, [illegible] Folkingham, Martin, Metheringham, [illegible] nards, Coningsby, [illegible] Mary), Fulstow, Hogsthorpe, Imminghan [illegible] Mareham-le-Fen, Market Rasen, Newton-o [illegible] Revesby Bridge, Saltfleetby (All Saints), Sutton-on-Sea, Tetford, Tetney, Theddlethorpe (All Saints), Toft Newton, Woodhall Spa.

Middlesex.—Finchley B.

Norfolk.—Freebridge Lynn, Diss, New Hunstanton, Wells.

[illegible] Flore, [illegible] edon, [illegible]

Nottinghamshire county and city.—Carlton-on-Trent, North and South Collingham, Colston Bassett, North Leverton, Tuxford.

Oxfordshire county and city.—Bampton, Bloxham, Burford, Chinnor, Clifton Hampden, Cropredy and Thame.

Shropshire.—Clun.

Somersetshire.— [illegible] be Down, Dulverton, Dunster, Ilminst [illegible] gport, Milborne Port, Minehead and P [illegible] Wellington, Weston Zoyland, Williton [illegible]

[illegible] (Seisdon R.D.).

[illegible] Alderton, Earl Soham, Peasenhall [illegible] nd, *Southwold, Wangford, Wrentham* [illegible]

[illegible] D.s; Banstead, Coulsdon and [illegible] erhead U.D.s.

[illegible] Cuckfield U. and R.D.s, Bexhill, [illegible] attle, Hailsham, Uckfield R.D.s.

Sussex (West).—Barnham, Eastergate and Yapton, Cowfold, Haslemere (area adjoining Surrey border), Selsey, Storrington, Worthing district.

Warwickshire.—Bideford-on-Avon, Hampton-in-Arden, Meriden R.D., Marton, Southam R.D. (with the exception of Southam and adjacent parishes), Stratford on Avon R.D.

Westmorland.—Ambleside, Milnthorpe, Burton, Arnside and Kirkby Lonsdale, Bowness, Windermere and Staveley, Grasmere, Glenridding, Kirkby Stephen, Kendal.

Wiltshire.—Aldbourne, Bradford-on-Avon, Broadchalke, Castle Combe, Great Bedwyn, Littleton Panell, Mere, Sherston, Sutton Be [illegible] ge, Codford St. Mary, Fovant, Hindon; Mc [illegible] Shrewton, Tisbury.

[illegible] House district, Malvern district.

[illegible] -Hornsea, Bubwith, Elvington, Escrick, Holme-on-Spalding Moor, Leven, Middleton-on-the-Wolds, Rillington, Roos, Stamford Bridge.

Yorkshire (North Riding).—Aldbro St. John, Ampleforth, Aysgarth, Coxwold, Danby, Easingwold, Tollerton, Hawes, Helmsley, Grosmont, Hutton Rudry, *Stokesley and Great Ayton*, Kirby Moorside, Kirklington, Knayton, Leyburn, Newsham, Reeth, Thornton-le-Dale, Topcliffe, Welburn.

Yorkshire (West Riding).—Harrogate.

Anglesey.—Beaumaris B., Llangefni and Menai Bridge U.D.s, Llanfairpwll and Bodorgan (Aethwy R.D.), Twrcelyn R.D.s (with the exception of Cemaes Bay) and Valley R.D.

Breconshire.—Llanwrtyd.

[illegible] gan, Crosswood, Henllan, [illegible] Llangadock, Llanybyther, [illegible] Bettwsycoed, Conway, Criccieth, [illegible] ama [illegible] (ar [illegible] (ar [illegible] Llanelian-yn-Rhos), Old Colwyn and Rhos-on- [illegible] adjacent areas of Pontfadog and Llanarmon [illegible] Bettws, G.G.).

[illegible] (Cardiff R.D.), Cowbridge Municipal and [illegible] clawdd (*Gower R.D.*), *Porthcawl* U.D.

[illegible] Barmouth, Corris, Towyn and Aber- [illegible]

[illegible] rt.—Caerleon, Tintern (Chepstow R.D.),

[illegible] Maenclochog, Newport, St. *David's*, [illegible]

Radnorshire.

DIRECTOR, DIVISION OF HOSPITAL FACILITIES, KING EDW
HOSPITAL FUND FOR LONDON

THE Select Committee on Estimates[1] recom. that "A uniform system of costing should be de as soon as practicable for the Hospital Servic England and Wales." What is meant by cost What are the objects and advantages of costin relation to hospital finance and accounting?

It is difficult to give an accurate and comprehe definition of costing. It may, for want of a bette described as a systematic record of the detailed tra tions relating to the various activities of a hos with a view to arriving at the total expenditure unit cost in respect of each ward, department, acti &c. Contrasted with financial accounts, cost acco endeavour to arrive at these figures by a *proces* detailed analysis, showing as it were a series of s income and expenditure accounts. The financial acco endeavour to arrive at the same total by the metho grouping the items of income and expenditure.

WHY COST ACCOUNTS?

The objects of cost accounts for hospitals may be st *briefly as follows:*

1. To provide the managing authority with knowledg the working or running expenses and costs of wards, de ments, functions, and activities, *with a view to (a) ob* and maintaining control over financial transactions, (*b*) increasing the efficiency of the administration.
2. To find out the elements of the working expenses a view to detecting waste of material, loss of time, an on, and to securing, where necessary, a planned reductio expenditure.
3. To ascertain that the proper relationship exists betw the expenses incurred and the services obtained in res of each activity.
4. To serve as a guide in the preparation of annual other budgets on a unit or departmental basis, and to en future policies to be founded on reliable information of work and *the cost of each unit or department.*
5. To record promptly the facts and tendencies of all activities with a view to enabling the maximum numbe patients to be treated for the least expenditure of mate labour, and time.
6. To show the cost of the staff as distinct from the of patients.
7. *To show the cost of special services as distinct* fr general services.

Among the particular advantages are these:

(*a*) With complete and accurate costs of maintaining e *activity, the apportionment* of expenditure between various classes of patients treated, and more particula between inpatients and outpatients, may be made on m reliable data than are available under existing arrangeme

(*b*) Cost accounts will show the nature and extent of *specialised treatments available. A* wide range of differen exist in this connexion, but under the existing arrangeme these cannot be allowed for in calculating the cost per b

Cost accounts combine the advantages of both t subjective and objective methods of accounting, t expenditure first being allocated to objects (war departments, *or activities) and then* to subjects (natu of expenditure) within the objects. They show also t extent to which each ward or department has be *called upon by others, and the* cost of the servic rendered to these latter departments. Each departme therefore charged with the expenditure it incurs, h direct and indirect ; and as the various departments subject to separate control responsibility for increases d decreases is more readily traced and brought to notice of those primarily responsible. The responsi- ity for the economical purchase of supplies will be th the supplying departments, and the responsibility the cost of consumption of supplies will lie, as it doubtedly should, with those who requisition and use em.

---

[1] Seventh Report from the Select Committee on Estimate Session 1948–49. *The Administration* of the National Hea Service. H.M. Stationery Office. 1949. See *Lancet*, 19 i, 1065.

Motives of economy are thereby made considerably onger. Further, the divisions into which the expen- ture is resolved throw into relief the separate services cidental to the activities carried on, and the whole the expenditure falling into each of these divisions is some extent correlated. A change in the organisation scope of any one of the services is thus reflected ly in the expenditure and unit cost of that service d has no effect upon the results shown by the other rvices. Hence from the viewpoint of control its precise fect upon the finances of the hospital is clearly bservable.

Again, with the aid of cost accounts it is possible to scertain the differences which arise from varying con- itions, and, by an intelligent study of the constituent lements of cost in each case, to consider methods by hich, without in any way impairing efficiency or limiting he number of patients treated, economies may be ffected.

These arguments in favour of the costing system now ecommended by the Select Committee on Estimates ll have some weight, though this varies in different ases. All of them together, however, are less important han certain indefinable, but nevertheless very real, dvantages resulting from a system of accounts which oncerns itself with matters of real interest to a keen nanagement and which leaves non-essentials alone. The lifference between a management which is kept con- inuously and well informed, and one which is uninformed, r half-informed, can no more be covered by specific oints than the benefits of a good education can be overed by giving isolated examples of its practical use. The steady flow of relevant and reliable data through he minds of the management cannot fail to generate n understanding and enlightened comprehension which will work itself out in sound policies that would otherwise e much less likely to materialise.

PRESENT DEFICIENCIES

A statement of the objects and advantages of cost accounts largely reveals the deficiencies and limitations of the present system from the viewpoint of administrative control. Any hospital recording system concerning financial and administrative activity is not productive, nor does it fulfil its potentiality for good, unless it furnishes the basis for an analysis of results which may be used by the management for purposes of control.

The present system of financial accounts throws very little light, from a practical standpoint, upon the causes which have produced the result it shows. A hospital comprises a large number of departments and activities, in which the conditions are fundamentally different; but the records do not show the expenditure incurred by each, and so it is not possible to judge the comparative economy of these various departments. The total cost of treating a patient in each of two wards in a hospital may be identical, but the items making up this cost in each case may vary to a remarkable degree.

Another serious deficiency of the present system is that the natural division of overhead expenditure is not shown. For example, the heating service comprises wages of engineer and boilermen and the price of fuel, water, and supplies of oil and other materials necessary for its maintenance. In order to ascertain the separate cost of this service—and it is essential that this cost should be known—all expenditure, whether direct or indirect, that is incurred upon the service has to be brought together into one account. At present, the expenditure on heating is diffused throughout the accounts—e.g., wages (under salaries and wages, other officers and employees); fuel (under fuel, light, and power); water (under the heading for water consumed throughout the hospital); and materials for repairs (under maintenance of buildings, plant, and grounds). Expressed in this way the statement of expenditure on the individual items has no real significance; for the items cannot be considered in relation to any service whereby their efficiency per se and their efficient use can be measured.

It has been said that hospital expenditure depends on hospital policy. This is a dangerous half-truth; the policy may be quite sound, but the administration by which it is carried out may be inefficient and extravagant to a degree. The form of accounts in use should be such as will bring the facts to light and so enable criticism to be usefully applied.

Disabilities

35. SUBARACHNOID HÆMORRHAGE

WHEN I woke on the morning of Dec. 30, 1939, I rolled over in my camp bed and stretched vigorously. After many civilian years I had been back in the Navy since August, my boss was my oldest friend, I was doing a job never done before by any Naval officer, so despite my ignorance I could hold my own with the crustiest captain, and I was thoroughly enjoying myself. I was 39 and very fit. There had been 20° of frost that night on the top of the hill behind Chatham, and the boards of the unheated Army hut kept out the blast only where they joined. As I moved I felt an ache and cursed the hut for landing me with a stiff neck. But the ache soon developed into a pain, then quickly into a blinding headache and I realised that something odd had happened. I had just enough time to fling on some clothes and stagger 15 yards to the operations room before I collapsed. The duty corporal, dutifully alarmed, rang the R.N. hospital and I was laid out to wait. The pain was now intense; I shivered violently. At last the ambulance came; the young R.N.V.R. doctor found it difficult to write down my particulars, for by now I was barely conscious and certainly not clear-headed. I cared little who was my next-of-kin, what my age, or where I lived. I do not remember arriving at the hospital, and little of the first day except great waves of pain, mercifully relieved by coma; the surgeon commander could not have had much help from me in making the diagnosis: if I answered any questions I could not have been coherent. Nor can I remember the first lumbar puncture. I had it at 6 P.M., and the cerebrospinal fluid confirmed the diagnosis at once. From the second day I would beg for more, and for morphia. Each puncture brought inexpressible and immediate relief, but after a few hours the pressure rose, and the pain returned. My eyes could bear no light, and there was a red haze round everything. In all I had five lumbar punctures—on the first, second, third, fifth, and seventh days. My later memory put the number well into double figures, but this may have been suggested by the enormous scab which came off in my first real bath.

In spite of all this I had no idea that I was seriously ill. Not until a visitor assured me that I *would* get better did it occur to me that I might not. Even then I never thought of it again.

* * *

It must have been during these early days that my dreams began. Hallucinations might be a better word, for they were so vivid that I could not distinguish them from reality until they had stopped. Although I was not aware of it, the war must have been on my mind: it came into every dream. I remember them all except the first, which, I was told later, I related at the time to the consulting neurologist—though I do not remember that either. It was about naval officers riding fish, perhaps an unconscious forecast of the "frog-men" of 1945. Another one distressed me intensely because some important plans, which only I could deal with, were missing. The clever chief sick berth steward gave me a large piece of paper, saying all the right things, and I was pacified. Once I was one of a party inspecting gun-sites in Sussex. It consisted of the gunnery commander (my friend in real life) and the King himself (I had served with him in the first war). We went to Rye (where I had lived 20 years before) and in the hotel I broke up the party by having a subarachnoid hæmorrhage. The King was most concerned and very kind. Another dream put me at the back of a room in which was a huge, brilliantly lit glass tank with several corpses in R.N. uniform swaying to and fro through the water. Unaware of my presence, some men—dark sinister shapes against the lighted tank—were watching this intently. I knew them to be enemy agents and slipped away to report.

The most exciting dream was thoroughly mixed up with reality. Once again the enemy was up to some deadly stratagem and had to be foiled at all costs. I started to get out of bed. Two raw young stewards had been set to watch me at night and they made the mistake of using force. As will be seen later, I responded only to cajolery. Held down on my back, I hit up at one of them and my knuckle split his lip and crushed his nose. It must have hurt. He let go and I turned on the other, who did not wait, but fled. First blood to me: in my dream they were in league with the enemy. I was out of the room in a flash and into the bathroom which I barricaded. The alarm had now been given and more stewards were sent for. My dream told me, then or later, that I must go to a certain barber's shop where I should find some men in white coats pretending to cut hair, though they were in reality dangerous spies. So I came out, to be confronted by four white-clad men. The battle began. It was not a fair fight, although four healthy men were against one very sick one, because I was filled with an astonishing strength and hit very hard, whereas they could only grapple. One by one they fell, or withdrew, leaving me gasping for breath but a victor, at my feet the bodies of the slain. I remember a feeling of triumph at having narrowly averted a disaster. The night sister came along now. I liked her, for she was sweet and kind and I knew her instantly: enemy agents were invariably swarthy, squat, and hideous. For all she knew I destined her as my fifth victim, but she put her arm round me and said "Come to bed now, there's a good boy"; and I went like a lamb.

That was the last dream. Lumbar punctures went on, with blessed relief. The headaches became less intense and less frequent: at night they were dispelled by 'Veganin' and tea. On about the tenth day I came off the danger list and on the fourteenth began to get up. After 3 weeks I was transferred, shaky and tired, to another Naval hospital, where I was admitted to the "bin." This may have been a clerical error, for after a few days I was offered a transfer to the medical ward; but by then I was finding the company so agreeable that I refused it. My reflexes were tapped or scratched—they were all over the place—and one psychiatrist put me through an appallingly stiff test of mental arithmetic in which I astonished myself by making no mistake. There was little wrong with my wits. I felt no worse than anyone who has been seriously ill—just ca tired and with poor appetite; but progress was stead

After 3 weeks there I went to Brooksby Hall w had been turned over by its owner for use as a Na convalescent home. We had Lord Beatty's cook butler; I had his bed. We were looked after by l lovelies, one of whom played and sang like an A pub within easy and pleasant walking distance delicious cherry brandy. I was sorry when I was gi three months' sick leave.

My strength increased and I started a wangle to my job back. It would have succeeded but for w was later described as an anatomical accident. afternoon in a cinema I began to feel uncomfortabl my buttocks and down the left leg. I could not sit When we came out I kept stumbling, and as I wal home my left foot seemed to be out of control. T night was bad. I could neither sit, lie, nor stand without a maddening discomfort. There was no p So, although I knew it would seal my doom, a call w out to the R.N. Hospital, Chatham.

My old friends, the surgeon commander, the c steward, and, to my delight, the night sister, now day duty, formed the reception committee on landing. My room was blacked out and the appara for a lumbar puncture was on the trolley. They expec trouble and were ready for it. I mumbled rat thickly that this was something quite different, but needle went in just to make sure. It acquitted me, blinds went up, and perhaps the stewards, rubbing th jaws, breathed again. It was soon decided that a sm clot had broken away from the scab inside my head had *floated along in the blood-stream until it entere* small vessel and jammed, causing hemiplegia with effect of a mild left-sided stroke. My face was immo on *that side, my speech blurred, and I could use my* hand with difficulty. There was no treatment, exc that for a week I was given a sedative every 4 ho through the day and knock-out drops at night. La on my private doctor, hearing what I had been havi said "Good God, that's not a sedative, it's an an thetic." I hardly ever woke. A heavy A.A. batt nearby would sometimes open fire, but I often slept At the end of the week I was taken before the surg captain with the result I expected. A nice touch in congé was the warning that if I stayed in the hospital af the date of my invaliding, it would cost me 12*s.* 6*d.* a d

Inactivity at home through the days of Dunkirk w almost unbearable. Strength came but the paraly remained. My speech recovered first, then the han but my foot dragged badly and even worse when I w tired. My face remained very stiff; I stopped smilin even when there was anything to smile at. Anoth symptom was a loss of emotional control. Not that flew into rages or burst into tears, but if I read somethi moving, or in a theatre saw a particularly movi scene, I could barely control myself: tears would co to my eyes, and my stomach would shake. Life beca intolerable with nothing to do. My civilian employe denuded of staff, took me back in June, six mont after the hæmorrhage. It was pure charity, for at fi I was useless. Two hours from door to door—five af one air-raid—was too much. I was desperately ti every night, my foot dragged, and only complete rest weekends kept me going. After six months or so began to pick up, and by the end of another year I co hold my own. I had been told that there was no answ to my errant blood-clot and that I should have to w for other vessels to take over the functions of the clogg one. Perhaps this was now beginning.

My 100% pension was reduced in the third year a again every year until the seventh, when I was given £ and told to go away. I could hardly complain, for then I was as fit as the next slightly unfit man, and r ly loss was the constantly recurring cost of repairs to left shoe. But "final settlement" was perturbing. hat," I asked, "if I get another hæmorrhage?" ey said that if I did, it would have been caused by events of 5 minutes, 1 minute, or even 10 seconds t, but not those of 1939.

o this day my control of the left foot is not perfect l my face is a little wooden. When very tired my leg sometimes tingles and twitches, especially in bed. t I take no precautions. I work hard, sometimes very d; by inclination I play no games, but I can walk day at my own pace. I sometimes carry heavy tcases; not long ago I decorated my flat, which found the weak spots in my shoulders and back. I can sit late and take a party with the next man—in short, ave written off all my troubles. But it sometimes es me to think that this dangerous and painful illness s as nothing, in its consequences, compared with the tuitous sequel, which was neither dangerous nor painful.

Public Health

Poliomyelitis

NOTIFICATIONS in the week ended July 16 were: poliomyelitis (73), polioencephalitis 5 (4), figures for the previous ek being in parentheses. Thus the rise in incidence which was nporarily arrested last week has set in again. Cases were dely distributed, but except for 2 in the Wigton district of mberland there were none north of the West Riding. ly one case was reported in the eastern counties. Multiple es (poliomyelitis and polioencephalitis together) were orted from: London 13 (6), Berkshire 2 (0), Cheshire 3 (2), rnwall 4 (5), Cumberland 2 (0), Devon 9 (11), Essex 3 (1), oucester 6 (3), Hertford 2 (4), Lancaster 7 (5), Leicester (1), Middlesex 11 (5), Southampton 14 (2), Surrey 4 (1), ssex 2 (1), Warwick 2 (3), Yorkshire, West Riding 19 (10), amorgan 4 (3).

The rise this year closely parallels that of July, 1947, en an "unprecedented prevalence" was forecast; once ain an unusually high incidence is to be expected, though ere is a definite possibility that the curve will flatten out. p to now the large centres of population have not been iously involved.

Poliomyelitis Film.—A 60-minute film, "Polio: Diagnosis d Management," produced by the Crown Film Unit in 1948 r the Ministry of Health and suitable for general-practi- oner audiences and nursing, physiotherapist, and public- alth staffs, is obtainable on 35 and 16 mm. on loan om the Central Film Library, Imperial Institute, South ensington, if the organiser has his own projector; otherwise can be shown on the Central Office of Information Mobile lm Units to professional audiences who can provide properly blacked-out hall, by application to the Regional lm Officer of the C.O.I.

Tonsillectomy.—In the memorandum on poliomyelitis medical officers of the Ministry of Health (*Lancet*, 1947, 155) the following statement was made: "There is, wever, overwhelming evidence that a recent tonsillectomy creases the risk of a child contracting poliomyelitis, parti- larly of the bulbar type. Prevalence of poliomyelitis in an ea should therefore be an indication for the postponement operations on the nose and throat whenever possible." e evidence was summarised by Glover (*Mon. Bull. Min. lth*, 1948, 7, 150). Surgeons should clearly take the local evalence of poliomyelitis into account when considering e desirability of operating on a particular child.

The June Quarter

The fall in the stillbirth and infant-mortality rates in ngland and Wales continued during the second quarter of is year. The stillbirth-rate (22·7 per 1000 total live and ll births) was the lowest ever recorded for a June quarter, nd equals the low record for any quarter set up in the eptember quarter last year. The infant-mortality rate of 0 per 1000 related live births was also the lowest ever recorded r a June quarter; it has been bettered only once—in the eptember quarter last year, when the rate was 28. The ve-birth rate was 17·7 per 1000 total population compared ith 21·9 and 18·8 in the second quarters of 1947 and 1948. he death-rate was 11·1 per 1000 total population: in the une quarter of last year it was 10·2, a record for the quarter.

In England Now

A Running Commentary by Peripatetic Correspondents

I SPRING to the defence of my unknown colleague in general practice who was metaphorically torn to ribbons by the local postmistress (see I.E.N. of July 23, p. 170). Does not this story exactly illustrate one of the most unsatisfactory features of the N.H.S.? When I was a boy and got a bit of grit in my eye it would never have occurred to me to take it to the doctor except in the last resort. I can remember numerous F.B.'s removed without difficulty by members of my family, by other boys, by schoolmasters, or, on one occasion, by a railway porter. The postmistress's F.B., admittedly a large one, could have presented no particular difficulty because the district nurse was able to remove it. Why then did the patient not go to the district nurse in the first place? More and more does a neurotic and "health-conscious" generation fly to the doctor about less and less.

* * *

Making out my weekly drug order under the N.H.S. gives me hours of happiness. In the past it was a humdrum affair. One merely listed in the order-book what was needed, adding the magic letters *N.(W.)F.* to the various liquores and misturæ pro infantibus, or the maker's name to the more recondite proprietaries, and the thing was done. Twenty minutes or less sufficed for it without putting any strain on the frontal lobes. I should mention that the job falls to me as medical officer of a small hospital without pharmacist.

Things are altogether different now. The head must be clear as well as the desk; the wits as sharp as the pencil. Here is work for a superior intellect. There are now not one but six order-books, and handsome big volumes they are, iridescent with their brightly coloured pages. The sky-blue one is for tablets and ampoules, and woe betide me if I enter any of these in the primrose book reserved for capsules, pastilles, pills, suppositories, and pessaries. Thoughts of homologous serum jaundice must not induce me to insert sera and vaccines on the deep yellow page less appropriately allocated to plasters and dressings, and to misdirect a proprietary article from its pink preserve to the white list of drugs, chemicals, galenicals, and gases is to court a charge of infamous conduct. Such are the hazards of a fascinating game.

It seemed a good opening move to enter in the white book the mists, pulvs, and ungs I had been accustomed to order, but that is promptly vetoed by Rule 10, which states that formulæ must not be written in the Purchase Order, but sent in as a Separate Statement so that "at a later date steps will be taken to ensure insertion in the Catalogue and the allocation of a Code Number and Unit of Quantity." The catalogue referred to is, like the order-books, in six bulky parts and is on the loose-leaf system—that is to say, the pages are clipped together now but will soon be all over the place as one hunts through them for the necessary clues. Of these pride of place goes to the Code Number, without which nothing can be ordered. Each number runs to seven figures, indicating that the sum of all articles obtainable already reaches millions, and no doubt it is going to soar steadily towards the billion mark as more and more code numbers are allocated.

By comparison, the insertion of the code number of the hospital on the pages of every order (Rule 8) is simplicity itself. There are but six figures here, showing clearly that the hospitals, dispensaries, &c., in this region are to be counted only in hundreds of thousands. This highly organised numerical system should at once make redundant the names of individual hospitals, many of which are either pompous or disagreeable anyhow. It should puzzle the enemy too in the event of war.

Another essential clue to be sought for is the Unit of Quantity. Let us see how it applies in the case of that very humble but necessary article, the cork, a few dozen of which in different sizes used to satisfy the needs of all my bottles over a long period. A chase often sidetracked on a false trail at length runs them to earth in part 6 of the catalogue, page 104, where the code numbers lend the poor things rank and dignity equal to that of the proudest mega of penicillin. Rule 5 (e) puts an end once and for all to the slipshod method of ordering a bag of mixed corks. Each of 11 sizes must now be ordered by unit of quantity, in this case a gross, so that to have some of each size means accepting over 1500 corks, most of which I am never likely to use. Then there is the matter of cost. For corks ordinary it is inconsiderable, but were I to require half a dozen corks red rubber I should be supplied with the inevitable gross at a charge of £1 2s. 6*d*. The column of charges is of course just a highly amusing abstraction in a health service wherein nothing is to cost anybody anything any more. Moreover a further stocking up of this item can be deferred until the summer of 1999.

Yes, the ordering of drugs, &c., has become a stimulating and thought-provoking exercise. To do it full justice I have set aside the whole of each Monday, and I hope the powers that be will devise other diverting tasks for other days of the week. It is really time our patients were told kindly but firmly that they can no longer expect the medical staff to devote more than one day in seven to their petty complaints, otherwise the essential business of the hospital must suffer.

* * *

The charming note on reflection and reminiscence by *my fellow peripatetic of July 9 and* Dr. Kennish's letter on hospital food in the same issue reminded me of an incident of my youth when we residents took more radical steps than merely to leave the dining-room.

We—and the nurses too—had fruitlessly and long protested over the appalling cooking to which we were subjected. On the eve of one hospital managers' meeting it was particularly revolting, so bad indeed that we sent the porter out for five fish suppers and a ewer of beer at a cost of 7*s*. 11*d*. The so-called Irish stew and the tapioca pudding we wrapped in several thicknesses of newspaper. Next day the senior resident waited on the managers' pleasure and, explaining the circumstances, presented the bill for 7*s*. 11*d*., requesting immediate reimbursement. When the storm subsided he apologised for the necessity of demonstration and unwrapped his two parcels in the middle of the committee table. Their overnight stay had not improved the appearance of these loathsome messes. The managers took this as a personal insult and intimated that he was dismissed. The senior resident thereupon threw open the door and dramatically pointed to two (empty) suitcases on the mat. "Gentlemen," he cried, with anger which he had no need to simulate, "all our bags are packed and we will see that the story of this is properly publicised among the graduates!" Capitulation was complete, and the cook was sacked forthwith. The nurses threw us a party to mark her passing. It was a *very* good night.

I am not advocating direct action, I merely record this incident to demonstrate the extreme lengths to which malnourishment may drive serious young men even at the critical start of their careers. That we were all Scots may have had something to do with it, for it is notable that your correspondent criticises the eating habits of the *English*.

* * *

It was about noon when I—the weary wife of a wearier G.P.—came round from the anæsthetic. It had been an acute appendix, with the usual distressing symptoms and a dawn rush by ambulance. Several pillars of the practice had broken through the cordon of nurses and were sitting about commiserating. Lacking imagination they did not realise that so soon after a surgical assault the patient's whole world is an aching and flatulent tum. The Vicar was different. He made witty cracks about tombstone inscriptions of the late century and left me amused and comforted. The pillars were solid, as one would expect, and as I lay there it seemed to me that the only thing that would shake them would be if my gaseous body rose gently from the bed and hovered at ceiling level while anxious nurses stood below with flatus tubes. I kept a firm hold on myself—both mind and suffering bod—and soon a nurse came and removed the pillars. "How did they get in?" she asked. "I'll get you a flatus tube. Would you like an injection?" Dear nurse, I watched the bubbles winking at the brim and felt that not even nylons, cigarettes, or black-market whisky could ever repay you.

Letters to the Editor

OSTRACISM OF THE TUBERCULOUS

SIR,—Dr. B. G. Edleston (July 16) does a valu service by drawing the attention of the medical profe to the ostracism suffered by the tuberculous. Ther no doubt that well-intentioned but ill-judged prop has produced grave misconceptions concerning the na of tuberculosis and that these have affected both the public and also many members of the medical allied professions whose work is not directly con with this disease. I recently heard of a case in w a patient in an infectious diseases hospital was foun have pulmonary tuberculosis. The matron of hospital immediately asked that the patient should moved because there were children in the hospital, also because some of her nurses were a bit run do This matron was an intelligent woman, and presuma she would have accepted a case of smallpox or typ without question ; but pulmonary tuberculosis. . . !

I would stress that we as a profession must a the responsibility for this state of affairs. Fifty ye ago consumption was regarded as invariably fatal, nobody bothered much about infection. It is med propaganda which has completely reversed these id and has led to the view that tuberculosis is highly in tious but easily curable if recognised early. Noth could be further from the truth, and although s publicity may cause people to rush to the mass rad graphy unit, so that their disease may be discove early and "cured," it imposes an intolerable burden the ordinary tuberculous patient. *If such a patien* known to be attending a clinic for supervision, if health visitor calls, or worse still if he is suspected having been in a sanatorium, he is liable to be trea *as a pariah by his fellows*. Nowadays, when ev child who coughs is in danger of being X-rayed, ma cases of primary infection are discovered which forme would have passed unnoticed. No doubt this is a go thing, but the immediate result is that the parents lo round for some unfortunate consumptive whom they accuse of having infected the child.

In fairness to the tuberculous, those concerned w the prevention of tuberculosis must make a radi change in their propaganda. The fullest possible pu licity should be given to such facts as the low incide of the disease among children in tuberculosis coloni and the comparative rarity of marital infection. The who have wide experience in the examination of conta can state that the diagnosed case rarely spreads th disease, and that even the patient with a positive sputu is harmless if he takes simple precautions. The patien themselves should be taught to observe these safegua not merely as an attempt to make themselves less inf tious, but because, if they do so, they need have anxiety whatever about *infecting* others. If everyo in the community could be *taught* to cough into a han kerchief, there is little doubt that pulmonary tuberculo would be drastically reduced, if not eliminated.

Dr. Edleston is right in suggesting that the gene hospitals should give a lead by accepting tubercul patients to their general wards. The teaching hospita *in particular, should set an example to others, and* y they are some of the worst offenders. As the oppositi in these hospitals comes mainly from the nursing sta the following remark by Florence Nightingale (*The A of Nursing*) is of interest : "True nursing ignores inf tion except to prevent it. Cleanliness and fresh a from open windows, with unremitting attention to t patient, are the only defence a true nurse asks or needs. Today we may add a Mantoux test and an X ray—bu the principles remain the same.

Brompton Hospital Sanatorium,
Frimley, Hants.

A. F. FOSTER-CARTER.

SALARY SCALES

Sir,—May I support your correspondent “ Chairman ” last week's issue ? Now that hospitals are no longer on a charitable basis they must be run on the basis a business. If in business an employee is required employer decides what salary will attract the man woman he wants. If he gets no satisfactory ponse to his advertisement he reconsiders the matter, rticularly with a view to upgrading the salary ; and salary eventually offered is that which *will* attract person he wants.

Hospitals are being cramped by the new principle salary scales. For example, in my city I have little ficulty in getting domestic staff on the basis of the ary scales, but my colleague, the medical superin- dent of the mental hospital, which is some 4 miles t and off a bus route, has great difficulty. It is vious that if he was in private business he would mediately offer more to attract people ; he would ssibly even organise a bus service ; but with salary les laid down he cannot do that.

As a concrete example, we are having great trouble er cooks. Our nurses' home caters for about 500, d as the living conditions of nursing staff are by no eans good it is most important, to my mind, that at y rate their feeding should be up to the best standard. it a chef at a hotel can get several pounds a week ore than we are allowed to offer. When we advertised the salary scale, we got two totally unsatisfactory plies. Our present cook, whose salary was decided fore the Act came into force, is leaving because the lary is too low.

No business could be successfully run on this basis. business would immediately get a cook and pay the lary required, and it seems to me that if hospitals are ot to be inhibited they must be given full licence to gage people at the remuneration required to obtain e person needed at the particular hospital for the rticular job. Salary scales are very good things, rovided they are regarded as a minimum ; but when ey are absolutely fixed and rigid they become a enace.

SUPERINTENDENT.

⁂ This subject is discussed in a leading article.—ED. L.

FOOLPROOF BLOOD-TRANSFUSIONS

Sir,—In his erudite letter of June 18 Dr. Wiener rites of mishaps due to occasional errors by a highly rained technical staff. The chief dangers of blood-ransfusion, however, lie in its wide use by doctors who ave had no adequate apprenticeship in grouping, collecting, storing, transporting, and administering blood, nd do not fully recognise the risks these operations nvolve.

Clinicians would be less confident in the safety of lood, and therefore more eclectic in its use, if they kept n mind the many possibly weak links in the chain of ts production. I have seen errors, for example, occur here the donor's blood-group was inaccurately recorded ecause infected serum was used for grouping. (All est sera should, I think, be labelled with the details of heir agglutinins and not only of their respective group-gglutinogens.) Or defects in the blood—arising either rom old age or infection—may have been masked by haking. (Once put in store, a bottle of blood should ot be shaken until a competent observer has carefully xamined it for evidence of abnormality.)

Assuming the blood itself to be beyond reproach, here are still risks in transfusion which are insufficiently ppreciated. The idea that large quantities can be ransfused rapidly without danger is based on war xperience with previously healthy young men, and is napplicable to the aged or chronic sick, for whom the choice of fluids, and the amount and rate of their administration, need careful consideration. A single pint of blood, especially if fresh, will often improve a patient's condition sufficiently to allow the *vis medicatrix naturæ* to complete the cure ; but in such cases the likelihood of benefit must be balanced against the risks inherent in transfusion. For the less expert, there is much truth in the saying that blood should not be given at all unless five pints are needed. It has to be remembered that all reactions—and they are not as uncommon as they should be—increase the burden borne by the patient. Even a mild reaction may provoke further hæmorrhage in a patient who has recently bled, and every known precaution must therefore be taken where a person has been previously transfused or may require transfusion later.

Blood-transfusion has in recent years developed into a mass-produced remedy which daily presents fresh problems. In the hands of experts it is virtually safe, and very valuable ; but there is little doubt that today, in this country as elsewhere, many deaths supposed to have occurred “ in spite of transfusion ” have really been *caused by it.*

Administration of fluids is not a duty that should be “ relegated ” to inexperienced juniors. It is not just a problem of minor surgery. In fact, there are few risks in transfusion when the doctor fails to insert a needle or cannula into a vein ; they begin to mount once he succeeds.

London, N.4. I. H. MILNER.

HORMONE TREATMENT OF THE SEXUAL OFFENDER

Sir,—The article of June 11 by Dr. Golla and Dr. Sessions Hodge is of interest to me since it confirms my initial observations on the value of œstrogenic preparations in the treatment of sexual offenders.

Since 1940 I have used stilbœstrol in the treatment of sexual offenders and for inhibiting libido in sexually aggressive psychiatric males committed to mental hospitals. I prefer stilbœstrol because by oral administration I can better control and regulate dosage to meet individual requirements. In my original article I reported that the degree of the gynæcomastic reaction invariably produced in males receiving stilbœstrol closely parallels the extent to which the anterior-pituitary gonadotropins and the 17-ketosteroids are depressed the extent of the degeneration in the cells of the seminiferous tubules, the inhibition of spermatogenesis or azoöspermia, and the degree of suppression of libido and the patient's ability to mechanically stimulate penile reaction. As the breast reaction resolves, libido reappears, degenerative changes in the tubules cease, and the gonadotropins and 17-ketosteroids increase. However, when stilbœstrol is administered in large dosage—5 mg. over an extended period—atrophy of the testes results and the changes in the size of the testes are permanent.

The need for an objective therapeutic reaction to indicate the adequacy of therapy is particularly apparent in psychiatric male patients. In this group of patients 1 mg. of stilbœstrol is usually sufficient to depress libido and maintain gynæcomastic response. Here the advantage of stilbœstrol-induced testicular atrophy over castration is that the climacteric symptom is avoided : furthermore, any degree of testicular atrophy may be produced.

The target point of stilbœstrol action in suppressing libido and penile reaction appears to be, as Dr. Spence (June 25) presumes, the inhibition of anterior-pituitary gonadotropin production. This could be tested by administering stilbœstrol to the eunuchoidal patient with infantile atrophic testes, normal or high gonadotropins and androgens in the urine, and normal libido. We studied the comparative effects of ethinyl œstradiol and methyl testosterone in a recent surgical castrate with normal libido. In this patient both hormones were of equal value for the flushes and sweats, but ethinyl œstradiol *failed to produce the sense of "well being" and metabolic balance* which is maintained with methyl testosterone. The libido of the patient practically ceased while ethinyl œstradiol was administered. In view of the patient's progressive weakness and weight loss during the period of œstrogen therapy we attributed diminished libido to his constitutional state; we have found that in patients with severe male hormone deficiency the general constitutional effect of methyl testosterone must be established before libido is stimulated.

The report by Dr. Golla and Dr. Sessions Hodge clearly establishes that castration for the treatment of sexual offenders should be abandoned.

Philadelphia. CHARLES W. DUNN.

PREGNANEDIOL IN URINE

SIR,—Your editorial last week on hormone assays gives an unfavourable impression of the value of pregnanediol estimation, which was discussed at the twelfth British Congress of Obstetrics and Gynæcology. My remarks in the discussion were not reported by you (p. 164), and I would like briefly to restate them.

Firstly, in answer to Dr. P. M. F. Bishop, the estimation can be, and is carried out in my laboratory as a routine test by the technical staff. No special arrangements need be made, and any specimen delivered here before lunch is reported on the same day. Secondly, in answer to Dr. G. I. M. Swyer and Dr. A. C. Crooke, the results are inaccurate if the amount of pregnanediol is calculated as per unit volume of urine. The output per hour, however, is apparently constant over a short period, and if the pregnanediol is calculated as per unit of time the results are much more consistent. My clinical colleagues find them of value. It is possible to arrive at the daily output on this constant hourly excretion without the necessity of obtaining 24-hourly specimens.

My series is as yet too small to justify publishing figures, but I hope later to present a full analysis of my results.

DAVID STERN
St. Woolos Hospital, Newport, Mon. Pathologist.

PAIN

SIR,—In his interesting observations on the rôle of the cortex in the perception of pain, a matter of great importance to us, Mr. Theobald (July 16) brings to notice how in the excitement of battle a man may be unaware that he has been wounded. The most striking account of this phenomenon is to be found in the pages of Lucretius, who describes it with the eloquence of a poet and the relish of a schoolboy.

> "So they record how the scythed chariots, reeking with indiscriminate slaughter, suddenly chop off the limbs, and the severed part that falls is seen to quiver on the ground; but such is the quickness of the injury and the eagerness of the man's mind that he cannot feel the pain; and because his mind is given over to the zest of battle, maimed though he be, he plunges afresh into the fray and the slaughter. And here among the horses is one unaware that his left arm, shield and all, has been torn off by the wheels and devouring scythes and lost; and from another the right falls, and yet he mounts and presses on; and there is one who has lost his leg, but struggles to rise, while hard by upon the ground the dying foot twitches its toes; and when a head is chopped off from a warm and living trunk, it keeps for a moment the look of life and the eyes remain open, until the last traces of the soul are given up." III, 642–656. (I follow Munro's punctuation in l. 646 and take *vis* and *mens* in l. 645 to be a hendiadys.)

The Romans illustrate Mr. Theobald's contention that susceptibility to pain varies with environment and heredity. With their fortitude, stoicism, ferocio punishments, and bloodthirsty amusements they m have been much less sensitive than we are, even thos us who have eschewed the blighting influences of " cinema, the lurid press, and aspirin," but not, I sup of "the other factors." *If* only Mr. Theobald could us what these are, we should be wiser men still!

Orpington, Kent. H. St. H. VERTU

EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—With regard to Dr. Lambert's letter in your of July 23, we have had some cases of poliomy here this year, the first two being notified in one hold on June 18 although the dates of onset were Jun and June 11. Local inquiries indicated that there been some transient obscure illnesses in the family in the neighbourhood, but there had been no recogni case of poliomyelitis in the borough since the previ October. These other cases could not definitely regarded as poliomyelitis, but it seems likely that poliomyelitis virus was present in the borough f *the end of May or the beginning of June.* On June (a Monday) I had a letter saying that two dead hedgeh had been seen three days previously lying in a ro which road happened to be within the affected area a little over half a mile from the two recognised case poliomyelitis. The road where they were found is n a public park. I asked the refuse collection departm whether dead hedgehogs were at all commonly found roads or refuse bins, but I was told the occurrence exceedingly rare. I then telephoned the Virus Refe Laboratory to see if they were interested in view of coincident poliomyelitis cases, but they told me t were not. Nothing further was therefore done.

I would add that two years ago when we had 80 recognised cases of poliomyelitis in the borough incidence of 35 per 100,000 population) there were reports of dead hedgehogs being found prior to or dur the outbreak.

Catford, London, S.E.6. Medical Officer of Healt

MALE TOADS IN PREGNANCY TESTS

SIR,—We were very interested in the article of Jul by Dr. Klopper and Mr. Frank. While welcomi the results of their experiments, we note that th did not refer to our account of 610 tests[1]—one of t first publications on this subject in Europe.

As we there observed, we found *Bufo vulgaris* equ satisfactory, but we soon changed to *Rana escule* for the following reasons: (1) *B. vulgaris* is n available in every season of the year; (2) *R. esculen* has proved more sensitive, giving a positive res with only 10–12 units of gonadotrophic hormone 5–6 units when hepatectomised); (3) *R. esculenta* more resistant to the toxic effects of some urines. Th findings may explain the high incidence of false negati from *B. vulgaris* as compared with our results (l than 1%).

We have now made over 1100 tests in all seaso Frogs caught in winter are less sensitive, requiri about 40 units of gonadotrophic hormone for a posi result. We have been able, however, to restore normal the sensitivity of hibernating frogs by givi them 1 μg. of thyroxine 24 hours before injection the urine. After administration of thyroxine posi results have sometimes been obtained with as little 5–6 units; but thyroxine does not increase the sensitivi of frogs caught in any other season.

PYOPERICARDIUM

ɪʀ,—Dr. W. E. Gibb's article[1] called to mind four s of pyopericardium seen in 1940–41 at the Royal pital, Wolverhampton, where they were under the of Dr. J. H. Sheldon.

ᴀsᴇ 1.—A man, aged 28, was admitted on Dec. 27, 1940, two days' history of fever and pain in the left chest. Signs onsolidation were present at the left base, and he was ted for lobar pneumonia with a standard course of sulpha-dine. On Jan. 5, 1941, pericardial friction developed, recrudescence of fever and precordial pain; two days signs of pericardial effusion were present, and diagnostic ration revealed a greenish purulent fluid, of which about ml. was withdrawn; this contained pneumococci. The hapyridine was continued, and after a further aspiration 20 ml. fever subsided and the signs of pericardial fluid ppeared.

ttempted aspiration on Jan. 21 showed a dry tap. At time he developed venous back-pressure, with congested k veins, tender enlargement of the liver, œdema of sacrum ankles, and ascites. He was treated with digitalis and salyl, and during February these features gradually sub-d. He was fit for discharge on March 6, and follow-up wed that he made an uninterrupted recovery and was ng a full day's manual work without dyspnœa, hepatic argement, or œdema.

ᴀsᴇ 2.—A welder, aged 20, admitted on May 25, 1941. ile at work a month previously he had been taken suddenly with severe gnawing pain in the front of the left chest ravated by breathing. He had become very breathless, l for a week had had a cough, worse at night, with greenish tum, and also a sharp pain in the left shoulder which npelled him to lie on the right side during sleep. There l been no fever, but his pulse had been noted to be very id.

On admission he was extremely pale and orthopnœic, with id and laboured respiration. The pulse was of poor lume, regular, rate 130 per min.; the blood-pressure was /80 mm. Hg. His neck veins were engorged and there was ting œdema of the lumbar region and ankles. There were ns of bilateral pleural effusion extending up to the third ace in both axillæ. The cardiac impulse was diffuse and apex-beat was palpable in the fourth intercostal ace, 3 in. from the midline. The area of cardiac dullness s enlarged, extending to 3 in. from the sternum in the ird space and blending with the dullness of the pleural usion below this; it was also enlarged to the right. The art sounds were distant, and pericardial friction was audible the second space. The abdomen was distended with cites, and the liver ballotable at the level of the umbilicus. e urine contained albumin and hyaline and granular casts. diography showed enlargement of the heart shadow. The esence of bilateral hydrothorax was confirmed. The white-ll count was 17,000 per c.mm. (polymorphs 88%, mphocytes 10%, monocytes 2%).

The pericardium was explored on the day of admission, but fluid was obtained. In view of the normal temperature e diagnosis seemed uncertain, and mercurial diuretics were gun. By June 3, however, the patient's condition had rther deteriorated; dyspnœa was considerable, and œdema d ascites were becoming more pronounced (resembling shberg's hypodiastolic cardiac failure). A second aspira-n of the pericardium produced a greenish purulent fluid, oz. of which was removed with great relief to the dyspnœa; e pus contained pneumococci.

The temperature now rose to 102–103°F. Chemotherapy ith sulphapyridine was commenced in standard dosage, and ricardial pus was replaced by sodium sulphapyridine suitably luted with saline; between June 5 and 15, altogether 35 oz. of pus was removed, and on June 24 a dry tap was ade. Meanwhile, on June 14, his course was interrupted left-sided spontaneous pneumothorax.

The last complication was infection of the originally sterile dema fluid on the left side. Weekly aspiration of 2–3 pints purulent fluid from this side was followed, on July 18, by tercostal drainage. The patient's condition improved; b-resection was performed on Sept. 20; and he was well ough to be discharged on Oct. 17. He has since recovered mpletely.

Cᴀsᴇ 3.—An infant of 15 months was admitted on June 15, 1941, with right lower-lobar pneumonia for which he received sulphapyridine. He improved rapidly, and the chemotherapy was discontinued after five days. He subsequently developed slight pyrexia (99°F) and was thought to have an empyema at the right base; but X-ray examination showed no evidence of this, and on July 2 he was discharged owing to a diphtheria outbreak in the ward. Three days later he was readmitted, waxy pale, and slightly cyanosed; there was clubbing of the fingers; examination of the heart revealed nothing abnormal apart from a tachycardia of 120 per min.; while in the chest there was poor entry at the right base, and bronchial breathing in the right upper zone. Exploratory needling of the chest proved negative. The white blood-cell count was 12,600 per c.mm. with relative lymphocytosis (56%); radiography showed no abnormality.

For the next three months the child went slowly downhill, with slight fever and attacks of severe tachycardia (up to 200 per min.) and cyanosis lasting a few minutes, and in the late stages gross enlargement of the liver and microcytic anæmia (hæmoglobin falling to 58%). Repeated examination of the chest showed bronchial breathing on the right side and occasionally showers of crepitations, but at no time were there signs of pericarditis. During second and third courses of sulpha drugs the fever subsided, but it promptly recurred after the course.

Autopsy revealed a well walled-off abscess in the pericardial sac posteriorly, smears of which contained many pneumococci.

Cᴀsᴇ 4.—A boy of 16 for a week before admission on Nov. 28, 1941, had had fever, loss of appetite, nausea, and headache. For five days he had had pain in the front of the right chest exacerbated by respiration. Fever continued (temperature 101°F) with profuse night sweats and considerable dyspnœa. Nothing abnormal was noted in the heart, but in the right chest anteriorly there was a small area of pleural friction. The urine contained albumin and a few pus cells. White blood-cells numbered 17,000 per c.mm. (81% polymorphs).

He was treated with sulphapyridine as a case of pneumonia, but though the pyrexia settled progress was unsatisfactory. On Dec. 2 the heart sounds were faint and the liver enlarged and tender. The next day examination indicated a large pericardial effusion. The liver was larger and there was some ascites and œdema of the ankles. Aspiration of the pericardium on Dec. 4 yielded a thin greenish fluid; one pint was withdrawn and 8 g. of soluble sulphapyridine in saline injected. Cultures of the fluid grew hæmolytic streptococci. Aspiration and replacement was repeated twice, the fluid becoming progressively more purulent; on the last occasion culture was sterile.

The pyrexia settled by Dec. 14, when a dry tap was made. After a long convalescence he was discharged on March 19, though even then there was some dyspnœa. I am informed that he died of constrictive pericarditis about eighteen months later.

These cases illustrate the varied clinical picture of the disease, and the difficulties in early diagnosis; Osler said that no serious disease is so frequently overlooked as pyopericardium. The most important cardiological finding is enlargement of the area of cardiac dullness; and percussion is most valuable. Hypotension, with low pulse-pressure are common, but "pulsus paradoxus" is neither a constant nor a very convincing sign. X-ray examination may provide no guide unless more than about 500 ml. of fluid is present in the pericardial sac; so exploratory puncture is often necessary. Even now it is difficult to see how the correct diagnosis could have been made in case 3, where the fluid was situated posteriorly in the oblique sinus.

"Hypodiastolic heart-failure" develops as a result of pressure on the great veins entering the heart.

The injection into the pericardial sac of alkaline sulphapyridine is risky; but in the 2 cases where it was performed the risk was justified by the results. No doubt penicillin given in the same manner will prove of great value.

I wish to thank Dr. J. H. Sheldon for permission to publish these cases.

MECHANICAL RESPIRATION

SIR,—I read with great interest Dr. Ritchie Russell's letter of July 23. I shall certainly get the publication he mentions to see whether the Americans are able to do more than we are. I mentioned the Oxford inhaler because many small hospitals might have an inhaler in the anæsthetic department and could therefore start treatment with it immediately. The inflator is better if it is available.

The McKesson resuscitator is timed with the respiratory rate which suits the patient, but we find most patients need practice in its use; once they have learnt to use it it is very satisfactory and its administration needs less skill than a manually worked apparatus; it is also a great saver of nursing time.

The illustration of the Stille respirator in my article shows the advantages—namely, the limbs are free for physiotherapy, if tracheotomy is necessary it can be done since there is no collar, and catheterisation is an easy matter. The chief disadvantage is that the machine is not fitted for all sizes of patient, and therefore I suggested that a greater range of shields should be obtainable.

I agree with Dr. Ritchie Russell that bulbar cases should not be treated in a respirator, but if respiratory failure supervenes the only treatment is postural drainage, mechanical respiration, suction of mucus, and perhaps in some cases tracheotomy in addition.

Western Hospital,
London, S.W.6.

URSULA BLACKWELL.

GROUP-ANALYTIC PSYCHOTHERAPY

SIR,—May I take up some of the points raised in your review of my book *Introduction to Group-Analytic Psychotherapy* (June 18)?

First, my approach is not "a mixture of psycho-analytic and 'supportive' measures." It is a consistent development of a method and an integrated body of concepts; and this book is an attempt to give an introductory account of these, since they were first put into operation ten years ago. This method of group psychotherapy represents a principle of orientation which I have designated "group analysis" or "group-analytic." I am aware that more recently a number of group therapists, both here and in the U.S.A., refer to their forms of group treatment as "group analysis" or "analytic group therapy" and the like, under which labels they practise a number of widely different techniques, differing not only from my own but also from each other. There are also a great variety of group treatments going on which may be called supportive, but neither the one nor the other of these types of approach has had much influence on my own, either historically or factually, so far.

In the second place you fall into the same error as most people, who think, when they hear of group analysis, that they must be dealing with a direct application of psycho-analysis. In my book I make a point of showing that this concept is wrong. It is as desirable for psycho-analysis as for group analysis that this mistake should be avoided.

Thirdly, I agree with you that the group situation exerts a strong supportive influence; so also, in my opinion, does the conductor, whether he knows or wants it or not, in his capacity as an archaic leader (father) figure. Any form of group treatment is bound to mobilise these forces in one way or another, whether blindly or deliberately. In group analysis these supportive energies are used principally to sustain the group in the analytic process, and not for their more immediate therapeutic effect, great as this is. Direct supportive remarks and actions play no significant part in my approach; and guidance, admonishment, reassurance, &c., with which you credit me, are not in my repertoire —not to speak of "punishing" actions or "removing difficult patients from the group." I think you fa distinguish between the group-analytic situation and episodes described in my book to illustrate dynamics, which took place in a totally different co This may be my fault for not having stressed the diff sufficiently.

Finally, as to "casualties"—by which is patients who stay away after one or two sessions. patients are not particularly common in my experi but I cannot say in the absence of figures whether are more or less common with me than with group therapists. Moreover, they do not leave spite of reassurance." On the contrary, their could easily be reduced if more influence were to induce them to carry on. The point I wanted apparently have failed) to make is that this self-selec process, just because it is allowed to take effect, good example of the diagnostic value of the situation, and its economy. In cases of this kind, economy is genuine because the consequences are wh favourable—to both the group and the particular (the "casualty")—provided the situation is handled and followed through by the therapist. I some illustrative examples in the book. The who is thus excluded by the group, or takes himself belongs usually to one of three categories: either h not amenable to successful psychotherapy at the ti or he needs special individual attention; or he (at least ideally) be absorbed into another group wh he might well thrive.

London, W.1.

S. H. FOULKE

THE PLACENTAL BARRIER

SIR,—The following results appear to be of s interest in relation to the passage of hormones across placenta.

A patient near term was found on vaginal biopsy to chorionepithelioma. The Aschheim-Zondek test was don dilutions of 1/10, 1/100, and 1/1000, using 2 ml. for e mouse. The 1/1000 gave a weak positive reaction, the ot strongly positive reactions. Delivery was by section, and first sample of the baby's urine, passed within 48 hours birth, was examined; undiluted, it gave a negative Aschhe Zondek test. Three months later the test was again negat The diagnosis in the case of the mother was confirmed p mortem.

In view of the great quantity of hormone in maternal circulation, these findings appear to show th the chorionic gonadotropin does not pass the placent

JOHN MURR

GRADING

SIR,—Many of the discrepancies in the grading consultants are attributable to the lack of criteria. T St. Helier Group Medical Advisory Committee beli that to be graded as a consultant a specialist s (1) have held an appropriate higher qualification for or more years, (2) have had training and experience his specialty, (3) be capable of practising his special without supervision, (4) have held a hospital appointment prior to July 5, 1948, and (5) be recogni by his colleagues, in his district, as a specialist.

In considering the senior medical staff of our h the committee find that they are divisible into three groups:

1.—Those who are entirely engaged in specialist hold an appropriate higher qualification, and have a hosp appointment as a specialist, should without question recognised automatically as of consultant status.

2.—Those not entirely engaged in specialist practice holding an appropriate higher qualification and a specia hospital appointment and recognised by their colleagues the district as specialists, should also have consultant

—(*a*) Those who hold a hospital appointment as a specialist gh not holding an appropriate higher qualification should, eason of their experience, be retained as senior hospital ical officers. (*b*) *In exceptional cases practitioners with* ecialist hospital appointment of many years' standing recognised by their colleagues in the district as specialists, not holding a higher qualification, should be considered consultant status.

he committee feel strongly that some classification the above lines should be drawn up, approved, and epted *to guard us, not only from the Minister and* satellites, but even, unfortunately, from some of our ı colleagues.

P. M. KELLY
Hon. Secretary, St. Helier Group
Medical Advisory Committee.

Parliament

QUESTION TIME

Anæsthetic for Dental Treatment

ir JOHN MELLOR asked the Minister of Health why, for tal treatment under the National Health Service, an sthetic was administered by a doctor without charge to atient on his list, whereas for similar treatment by a vate dentist, the same doctor charged the same patient a for such anæsthetic; and whether provision would be de for the right to receive an anæsthetic under the National alth Service to be the same in the case of treatment by a vate dentist as in other cases.—Mr. ARTHUR BLENKINSOP lied: Responsibility for providing an anæsthetic for ıtal treatment carried out under the National Health vice rests on the dentist who receives payment for the ninistration of the anæsthetic and makes his own arrangents with the anæsthetist. The treatment which a doctor equired to give a patient on his list does not include the ninistration of an anæsthetic at a dental operation, and re is nothing to prevent the charging of a fee for this vice where the dental treatment is given under a private angement.

Medical Examination of Teachers

Mr. ANTHONY GREENWOOD asked the Minister of Education w many local education authorities insisted upon candidates appointment as teachers being examined by radiography.— . GEORGE TOMLINSON replied: Some local education thorities require candidates for appointment as teachers undergo a medical examination before appointment, but lo not know how many require an examination by radioıphy. Mr. GREENWOOD: Would the Minister look into the ıtter again? In view of the importance of preventing spread of disease, would he consider publishing a list of authorities which do not insist on radiography, so that ndidates for appointment will know the advantage which ey are missing and parents will know the danger to which ildren are being exposed?—Mr. TOMLINSON: Most of the ndidates submit themselves for medical examination. am more concerned about mass radiography, if it is to be plied, being applied to teachers after they have done some ıching rather than before they have actually done any.

New Hospital for Basingstoke

Mr. P. W. DONNER asked the Minister of Health when ilding on the new Basingstoke hospital is likely to begin.— . A. BEVAN replied: I understand that the regional hospital ard is considering the provision of a new hospital in Basingoke, but progress must depend on its urgency compared th other calls on the available money and building resources. r. DONNER: Is the Minister aware that some £24,000 was luntarily subscribed in this town for a new hospital, and at there is deep dismay that apparently this money is w absorbed in a general pool, with little prospect of a new spital?—Mr. BEVAN: They would not have been able to ild much of a hospital for £24,000, or maintain it after it ıs built. Money has to be found, and had to be found fore the Act, for the maintenance of voluntary hospitals.

Mr. DONNER asked the Minister whether he was aware that e Basingstoke hospital service was now responsible to inchester group, which was responsible to the region, which turn was responsible to the South-Western board; that penses of operation had been increased by this system as well as by the appointment of officials and that delays due to this centralised control marred the efficiency of the service; and whether he would simplify control.—Mr. BEVAN replied: *If the hon. member will send me evidence of delays and* increased expense I will investigate them, but I am not prepared to consider unsubstantiated statements. Mr. DONNER: I will certainly send the Minister such evidence. Is he aware that the chairman of the hospital committee has resigned, and that the general view in Basingstoke is that the town is very much worse off since the health service was begun?—Mr. BEVAN: I doubt very much whether that is the general view in Basingstoke. At any rate there are between 10,000 and 11,000 voluntary workers in the hospital system, and this is the first resignation which we have had. Mr. DONNER: Is the Minister aware that if he visits Basingstoke he will be able to confirm the truth of what I have said?—Mr. BEVAN: I may even consider addressing a meeting at Basingstoke to find out what the people think about it.

Redistribution of London Doctors

Mr. J. F. F. PLATTS-MILLS asked the Minister if he was aware that in the borough of Finsbury there was only one doctor to every 3678 of the population, compared with one for each 2935 in Islington and 2429 in Holborn; and what action he was taking to bring the number of doctors in Finsbury up to the level of the best London borough.—Mr. BEVAN replied: Redistribution of the available supply of doctors in accordance with the best interests of the public must be done gradually. The method of remuneration under the National Health Service, coupled with the powers of the Medical Practices Committee to close over-doctored areas to new entrants, should be sufficient to bring about the desired result.

Obituary

RICHARD WALTER MARSDEN

M.D., B.SC. MANC., F.R.C.P.

ON July 10 Dr. R. W. Marsden died, aged 81, at his home in Withington, Manchester. He came of a family springing out of the Craven district of Yorkshire, but he himself spent nearly all his life in Manchester, where his father, Henry Marsden, J.P., was for several years a councillor of the corporation, and most of his medical work was done in the health service of the city.

In 1887 he took a B.SC. degree at the Owens College and in 1891 he qualified with the Conjoint diplomas. Having held a house-appointment at the Manchester Royal Infirmary, he went to the New Bridge Street receiving office, and thence to the Monsall Fever Hospital, where he became superintendent. A period in medical consulting practice followed, when his skill in fever work gave a special call for his services and during which he acted as physician to the Ancoats Hospital, and to the Consumption Hospital. In 1906 he was appointed superintendent of the Crumpsall Hospital and he held this post for 27 years. On the outbreak of war in 1939 he was persuaded to undertake work at the Parkside Emergency Hospital, Macclesfield, looking after disabled soldiers.

Marsden's writings are mostly about fevers, on which he wrote two books: his *Hints on Management of the Commoner Infections* appeared in 1906 and his *Practical Textbook on Infectious Diseases* two years later. He was a firm believer in the antipyrexial treatment of fevers by water baths. As a teacher he excelled, and "one feels it a pity" (writes a colleague) "that he did not have more to do with students. But in his hospital work the staff, *medical and nursing, had full opportunities* of learning from him much that was useful to them. I remember well how in his typhoid wards Dr. Marsden showed a rash which certainly was not typical, and, after allowing the students to make wild guesses, quickly settled the presence of scabies by means of a needle and microscope."

Up to the end he was an active member of the Manchester Medical Society, of which he was for 8 years treasurer. In 1928, as president, he gave an interesting address in Changes in Medical Practice in the last Forty Years. He was elected F.R.C.P. in 1929.

Dr. Marsden was twice married; first in 1916 to Mary Sharpe, who died in 1937. Their three sons are all doctors: one a surgeon lieut.-commander in the Royal Navy; another an assistant medical officer at the Manchester Skin Hospital; and the third a pathologist at the Pendlebury Children's Hospital. His second wife, Iris Beatrice Whittaker, survives him.

BRIAN RAIT-SMITH

B.A. CAMB., M.R.C.S., F.F.A. R.C.S.

Dr. Brian Rait-Smith, anæsthetist to St. Bartholomew's Hospital, died at St. Albans on July 14, aged 45.

After taking his B.A. at Cambridge in 1926 he completed his medical studies at Barts, where he took the Conjoint qualification in three years later. He held a resident appointment as anæsthetist there before he took his D.A. in 1935, joining the staff two years later. He also held appointments at the then British Postgraduate Medical School, the Brompton Hospital, and Papworth Hospital, Cambridge, and he was a consultant anæsthetist to the London County Council.

The last ten years of his life were spent at St. Albans where at the beginning of the late war he was transferred to Hill End Hospital. Of these years a colleague writes: "Hill End, at that time a mental hospital, was rapidly transformed into an E.M.S. establishment capable of dealing with every type of case. It was probably the only hospital in the country housing under the same roof full-scale orthopædic, thoracic, neurosurgical, and plastic units, while at the same time dealing with E.N.T. and general surgery. At all these branches of his specialty Rait-Smith was adept, and he did some excellent original work on the anæsthetic problems involved in the many new operations of cardiac surgery. Some of his observations were recorded in a recently published paper on the subject.

"The later years of his life were marred by continuous ill health of which he made light, and although he knew that a threat hung over his head he did not allow this knowledge to poison his outlook on life. An excellent teacher, he hated humbug and with puckish humour could deflate the most swollen-headed student in a few words, which however, left no permanent sting behind."

GEORGE ALEXANDER MACDONALD

M.D. EDIN.

Dr. G. A. Macdonald, a founder of the London College of Osteopathy, died on June 30 at the age of 57. The son of the late James Macdonald, at one time secretary of the Highland and Agricultural Society of Scotland, he qualified M.B. in the University of Edinburgh in 1914, and soon afterwards, as a member of the special reserve R.A.M.C., he was called up for service. With the rank of captain he served in India throughout the 1914-18 war.

After the war he studied for two years in the Kirksville College of Osteopathy, where he obtained the degree of doctor of osteopathy in 1920. Later he practised osteopathy in Edinburgh in partnership with his brother, the late Dr. Kelman Macdonald, and in 1925 he settled in London. His standing as an osteopath was recognised by his colleagues and he was for many years president of the British Osteopathic Association. He made a well-known contribution to his subject in *The Osteopathic Lesion*, written with W. Hargrave-Wilson and published in 1935.

G. E., to whom we are indebted for this memoir, writes: "Macdonald worked for the inclusion of osteopathy in medical practice. He looked forward to the time when all qualified osteopaths would be medically qualified as well. He felt a personal call to implement this aspiration, and in spite of opposition he took a leading part in founding, for medical men, the London College of Osteopathy, of which he was the first dean. He made a great contribution to osteopathy, not only in the skill with which he practised it but also in the high standard that he maintained in his work. Practice in London came slowly at first, but his sympathetic nature soon won him many friends, and once his practice was established it grew rapidly, simply because of the real benefit that his patients derived from his treatment. His kindness to his patients and his understanding them was great and good; his relations with the med profession were friendly and true. A real Sco loved his country and he spent his holidays in Perth

Dr. Macdonald leaves a widow and a son and a

CHRISTOPHER JAMES LEWEN SHARP

M.C., M.B. CAMB.

MANY besides old Londoners will have heard regret of the death on June 6 of Chris Sharp. E at St. Paul's School, where he was captain of and at Cambridge University, he completed his studies at the London Hospital after the last taking the Conjoint qualification in 1924 and his three years later. After holding house-appo at the London he settled in practice at the Devon of Sticklepath, where he was to spend the rest of his

L. N. J., who knew him pretty well for 45 year school, as a field gunner in the first war, as an u graduate, medical student, and doctor, writes: "I of Chris as a sensitive person of high courage, b generosity, and perennial good humour, who p games well and the piano better than most ama Coming of an artistic stock—he was a nephew of Sharp—he was fastidious with a critical faculty developed in many directions. It amused him to as a fool, but he was, in fact, very far from being bogus or pretentious persons had reason to drea bland Socratic questioning. Always convivial by —as a small boy he could drink twice as much as the rest of us—he nearly lost his life during the war through digging out a teetotal comrade unde and poison gas. For this and other exploits he decorated—much to his amusement. Whilst he w hospital I visited him. He was on the danger list the ward sister on tiptoe and with finger to lip beck me to the bedside. He was temporarily blinded, blistered, and had bronchopneumonia. 'How are y I asked fatuously in a whisper. 'Oh, I'm very near right, ol' boy,' he replied, 'and if I could get out of and have a pint I should be quite all right.' He an uninterrupted recovery."

Births, Marriages, and Deaths

BIRTHS

BALL.—On July 19, at Llwynypia, Rhondda, the wife of Ca H. C. Ball, R.A.M.C.—a son.

BENIANS.—On July 15, in London, the wife of Dr. R. G. Beni a daughter.

CALMONSON.—On July 21, in Manchester, the wife of Dr. A Calmonson—a daughter.

CHILDS.—On July 20, the wife of Dr. Michael Childs—a daught

FRASER.—On July 19, the wife of Dr. T. A. Fraser—a daughter.

GRAHAM.—On July 22, in London, the wife of Dr. Ian Graha a daughter.

HUTCHIN.—On July 18, the wife of Dr. K. C. Hutchin—a daug

JACOBS.—On July 18, in London, the wife of Dr. J. J. M. Jac a son.

LESLIE.—On July 19, at Sheffield, to Dr. Mary Leslie (née Bra waite), the wife of Mr. G. F. Leslie—a daughter.

LOVE.—On July 17, at Stockport, the wife of Dr. William Lo a daughter.

SWAN.—On July 15, at Storrington, the wife of Dr. J. F. S —a son.

TWINING.—On July 22, at Okehampton, the wife of Dr. D Twining—a daughter.

MARRIAGES

CATES—CLARKE.—On July 12, at Dartford, Bernard Cates, to Blanche I. L. Clarke.

GIBSON—WHITELEGG.—On July 14, in Guernsey, Richard Ed Gibson, O.B.E., F.R.C.S., to Margaret Chamberlain Whitele

MOSS—SMITH.—On July 16, in London, John Moss, M.B., to S Smith.

—On July 16, at Oswestry, James Alexa I.C., M.B., to Agnes Eugénie Sladden.

—On July 16, in London, Alexa , to Diana Rose.

WHITE—COOK.—On July 16, at Hatfield Broad Oak, John Ar Temple White, O.B.E., M.R.C.S., to Florence Cook.

DEATHS

CROSSLEY.—On July 20, Leonard Crossley, M.D. Edin.

DALRYMPLE.—On July 17, at Bude, Cornwall, Joseph Da C.M.G., O.B.E., L.R.C.P.E., lieut.-colonel, R.A.M.C. retd, aged

DAVIES.—On July 19, at Southsea, John Phillip Henry D M.A., M.B. Camb., D.P.H.

ROBERTSON.—On July 21, at Fort Augustus, John Joseph Rob M.B. Glasg.

SOUTHEY.—On July 21, at Maidstone, Herbert Watson Sout M.R.C.S., aged 81.

WILSON.—On July 18, at Normanton, Charles Haddon W M.B. Leeds.

Notes and News

NSULTANTS' AND SPECIALISTS' CONTRACTS

announcement by the Joint Committee which we arised last week stated that the Ministry of Health had that individual practitioners are free to leave untouched lelete from the whole-time contract any of the clauses are enclosed in square brackets. The question has been whether similar considerations will apply to the part-contract. In principle, the same considerations will to the part-time contract, but it will be appreciated n most cases the clauses enclosed in square brackets fundamental to the part-time contract.

GENERAL MEDICAL COUNCIL

RING the lifetime of the present Parliament two members been nominated by the King to the General Medical il. Mr. J. J. Robertson has sat with the council since Mr. J. J. Hynd was elected this year but has never part in the proceedings. Hard on his appointment urred to him that he might be infringing the statute of which forbids an M.P. to hold an office of profit under own. True, the statute is somewhat vague and does not ely define what is meant by an office of profit. Members G.M.C. receive 5 guineas for each attendance at a il meeting, and they are paid not out of the State but out of registration fees collected from the medical sion. Nor is it always clear whether offices established 1707 are held under the Crown within the meaning of Act. But the Attorney-General found Mr. Hynd's les not without substance, and on July 12 he introduced to protect Mr. Hynd and Mr. Robertson from their ical infringement of the law. Other M.P.s who have the council in the past are safe from penalties, as any s against them by now are statute-barred. The Attorney-al stated that the present holders must vacate their ntments and in future no M.P. would be qualified to hold office.

REW UNIVERSITY HADASSAH MEDICAL SCHOOL

April 23 Dr. Eli Davis described in our columns the undergraduate medical school which was opened in salem on May 17, with 45 students. At a dinner held in on on July 21 by the Friends of the Hebrew University rusalem, the Minister for Israel said that though the er of doctors in his country was three times as large as d generally be thought necessary, the number who young and vigorous was alarmingly small. The object e school was to meet the needs of the younger generation to provide doctors fully familiar with local conditions. ould contribute to the welfare both of Israel and of bouring countries. Sir Henry Cohen said that when university was opened in 1925 a research institute in biology already existed, and in 1938 the University-ssah Medical Centre came into being. All this time was a demand for an undergraduate school to train tants for doctors carrying on research, and also to give esearch-workers contact with the young inquiring mind. ing considered the curricula of various countries, the ersity chose that of Great Britain as its pattern, increasing ength to seven years; and in 1939 all seemed in train. the war intervened and the school had only now been ed. Having found a new freedom, he trusted that the ersity would realise that help from outside might be ral as well as material: as the real centre of the new the university must be independent of politics and siasticism of certain types; truth must be pursued out fear and expressed without hindrance.

of. Samson Wright, who presided, and who read a message couragement from Sir Henry Dale, O.M., said that even e recent difficult years the medical research departments e university had continued to receive help from the sh Empire Cancer Campaign and the Medical Research cil: when understanding was regained on the spiritual intellectual plane the rest would follow. The university's nt budget was about £700,000, of which its British ds had pledged themselves to raise £100,000, much of h would go to the medical school. He believed that the ersity, through the school, would serve not only Israel all mankind.

r. Redcliffe Salaman, F.R.S., recalled how, as an Army or, he had witnessed the laying of the university's foundation-stones in 1917. He described it as the one great focus of science and research between Rome and Pekin. Dr. A. Felix, F.R.S., said that though 500 doctors had arrived in Palestine this year their professional level was unfortunately not high—which was hardly surprising; and the immigrants of the next few years would be coming from countries where there were hardly any doctors. The difficulties in face of opening the school just now were enormous: any non-Jewish expert would have deemed it madness. But in all the ages Jews had made important contributions to medicine, and they would overcome the obstacles.

University of London

Dr. C. F. Barwell has been appointed to the readership in bacteriology at the London Hospital; and Dr. J. J. Pritchard to the readership in anatomy, and Dr. H. C. Stewart to the readership in pharmacology, at St. Mary's Hospital.

The title of professor emeritus of anatomy has been conferred on Prof. J. Kirk, on his retirement from the Courtauld chair at Middlesex Hospital which he has held since 1937.

At recent examinations the following were successful:

M.S.—branch I (surgery): C. J. Longland, P. P. Rickham *branch IV (otology, rhinology, and laryngology)*: L. F. W. Salmon.

D.M.R.—A. I. Black, J. M. Burbury, D. McC. Gregg, S. J. Hinds, B. M. Jacobson, T. M. Prossor, Ram Singh, Z. L. Szur.

University of Edinburgh

On July 20 the following degrees and diplomas were conferred:

M.D.—E. G. Barnes, A. E. Claireaux,‡ J. W. Fraser, A. D. Gillanders,‖† David Gilmour, J. S. Grant, Barnett Isaacson,‖ Marjory A. Keith,* C. K. McDonald, W. A. L. MacFadyen, Carmichael Mackie, A. B. Monro,‖ Mustafa Niazi, A. W. Williams, J. H. Young.†

C.M.—A. W. Wilkinson.*

Ph.D. (in the faculty of medicine).—Mohamed Mahfouz Abdel Aal, Barbara E. Clayton, Helen N. Duke, J. A. Loraine, H. C. W. Stringer.‖

M.B., Ch.B.—Mary H. Aitken, J. A. D. Anderson, Oliver Archer, P. G. Aungle,§ N. E. Awunor-Renner, J. S. Barrett, J. A. Beattie, M. H. Beaubrun, Boleslaw Bendkowski, J. S. Berkeley, L. H. Berman, W. F. Blair, Dorothy S. Bleakley, Halina Bobinska, D. H. A. Boyd, J. D. D. Brown, J. H. Brown, J. B. Brown, T. A. Brown, I. A. Cameron, I. H. Cameron, Margaret M. Cameron, J. H. Campbell, M. A. Campbell, A. J. M. Carlin, Marion L. Clark, Matilda J. Clerk, W. P. Cockshott, Neil Conley, John Cook, W. F. Coulson,§ Isobel B. Craighead, W. A. Cranston, Janet S. Darling, R. D. McC. Davie, A. R. Dawson, K. S. Deas, Catriona M. Dempster, Pamela M. Dodson, Alice B Doherty, Eleanor J. Durrand, Frances M. Falconer, Helen L. A. P. Fermie, Mary C. R. Fisher, H. M. Flett, Mary L. Fraser, J. A. G. Graham, P. W. Grant, G. H. Hardie, E. R. Harris, Muriel G. Hartley, Susan E. Herdman, J. A. Hislop, Sheila S. Hume, R. S. M. D. Inch, T. T. S. Ingram, J. J. Ironside, Ailine M. W. James, D. A. Johnson, I. M. Johnstone, Leon Kaufman, Margaret Kennedy, I. H. Kidd, Robert Kilpatrick,§ J. D. E. Knox, Arnout Koch, J. A. Krawiecki, Krechimir Krnjevitch, Janet M. Lamont, J. A. H. Lee, Anne P. D.M.R.D.—Agnes M. Macgregor, John Mackenzie, C. D. Preston, D. F. Ross.

D.M.R.T.—J. D. Crowley, John Milligan.

M.D. of the Polish School of Medicine.—Bronislaw Rozenblat, Stefan Grzybowski, Jerzy Klimczynski.

M.B., Ch.B. of the Polish School of Medicine.—J. S. Biskupski, Konstanty Maksimczyk, Alicja Lubicz-Sawicka, Aniela Szwede, Leon Buczek, Antoni Chrzaszcz, Cezary Cywinski, Jadwiga Dabrowska, Danuta Graczyk, Kaz [illegible] Kawa, Alina Klosowska, Gertruda [illegible] Tadeusz Krzyski, Wanda Kucha [illegible] Michal Matuszewski-Topor, Ludwika Sawicka, Bronislaw Skibinski, Marja Starczewska, J. F. Witek,

* Awarded medal for thesis.
† Highly commended for thesis.
‡ Commended for thesis.
§ With honours.
‖ In absentia.

The Cameron prize in practical therapeutics was awarded to Mr. Daniel Bovet, D.SC., director of the Istituto Superiore di Sanità, Rome, in recognition of his work on anti-histamine drugs.

University of Manchester

Dr. R. F. L. Logan has been appointed part-time lecturer in occupational health, and Mr. John Miller, B.D.S., lecturer in children's dentistry and preventive dentistry.

Royal College of Physicians of Edinburgh

At a meeting held on July 19 with Dr. W. D. D. Small, the president, in the chair, the following were elected to the fellowship:

D. E. Sands (Sutton), A. W. S. Thompson (Auckland, N.Z.), C. F. J. Cropper (Worcester).

Diplomas of membership were conferred on the following:

R. G. Lendrum, J. I. Lipschitz, R. W. D. Turner, R. M. M. Hunter, A. C. S. Iyer, A. P. Littlewood, W. Gordon, Muriel M. D'Souza, B. E. Cohen, J. H. Taylor, J. O. Craig, J. W. Farquhar, K. Rhaney, G. Mundel, D. Cappon, T. C. Noble, F. W. A. Turnbull, J. S. Calder, R. T. Ritchie, R. S. Walker, A. B. Sclare, J. D. Matthews.

Heberden Society

This society held its annual meeting at Oxford on July 15 and 16, when the Heberden Round was taken at the Radcliffe Infirmary by Dr. Sidney Truelove in the absence of Prof. L. J. Witts. Seven cases were presented for discussion by Dr. Truelove and members of Professor Witts's unit.

Edinburgh Post-Graduate Board for Medicine

On Tuesday, Aug. 2, at 4.30 P.M., in the anatomy lecture-theatre of the university, Prof. John McMichael will speak on the Principle of Venous Pressure Reduction in the Treatment of Heart-failure.

Payment of Part-time Consultants

A Ministry of Health circular (R.H.B. [49] 100) makes it clear that a part-time consultant who enters into contract with more than one regional board or board of governors, is to be treated, for the purpose of determining total remuneration, as though all his services were rendered under a single contract.

Appointments at Italian Sanatoria

Temporary appointments at the Forlanini Sanatoria in Rome and Naples are offered by the Instituto Nazionale della Previdenza Sociale to doctors from other countries who wish to study Italian methods of treating tuberculosis. Successful candidates will receive full board and lodging but they must find their own return fares and pocket money. Applications should be sent to the controller, education division, British Council, 3, Hanover Street, London, W.1.

World Health Organisation

Less than a week after the end of the second World Health Assembly in Rome the executive board of W.H.O. met at Geneva to implement the decisions taken at the assembly. For instance, the board authorised the director-general, Dr. Brock Chisholm, to negotiate for voluntary contributions to implement the supplemental operating programme for 1950, which is a part of the United Nations scheme for technical assistance to underdeveloped regions.

The board also authorised the director-general to establish a regional organisation for Europe, after obtaining the consent of the majority of European member states, and to establish a regional office and to appoint a regional director on the basis of recommendations of the regional committee and after approval from members of the board obtained by correspondence.

Poliomyelitis in the United States

At an emergency meeting recently called by the U.S. National Foundation for Infantile Paralysis and reported by British United Press, Mr. Basil O'Connor, president of the foundation, said that 37 States had already reported a considerable increase over the number of poliomyelitis cases last year, which was the worst for more than thirty years. In the week ending June 25, notifications numbered 409, making this year's total 2718: the corresponding figures at the same time last year were 309 and 2006 respectively. Since 1944 the average number of cases of infantile paralysis had risen by about 9000 annually. Mr. O'Connor disclosed that the foundation, using accumulated reserves, had spent more than $4,500,000 above the amount received in contributions last year. An emergency campaign for "epidemic funds" might be needed; for the only alternative would be a curtailment of the foundation's research programme.

R.A.F. Medical and Dental Branch Dinner

The annual dinner will be held at the Dorchester Park Lane, London, W.1, on Friday, Dec. 2. F particulars will be found in our advertisement columns.

International Nomenclature of Drugs

The World Health Organisation is to formulate a international nomenclature for new habit-forming and drugs. This action is being taken because of confusion by the same drug being marketed under more than one

Alvarenga Prize

The College of Physicians of Philadelphia have the Alvarenga prize for 1949 to Dr. O. H. W professor of surgery in the University of Minnesota, contributions to the ætiology and therapy of gastri duodenal ulcer.

Manchester Pædiatric Club

The fifth meeting of this club took place on July 18, Dr. Alton Goldbloom, professor of pædiatrics at University, delivered an address on Pitfalls in Diagnosis. The second annual general meeting will b on Sept. 27.

Ministry of Food

Mr. Morley T. Parry, chief sanitary inspector, Nor county borough, has been appointed food hygiene ad officer at the Ministry. His duties will include visiting authorities and advising them, and he will work und direction of Dr. W. A. Lethem, the Ministry's medical officer.

Society of Chemical Industry

The food group of the society is holding a symposiu Amino-Acids and Protein Hydrolysates on Sept. 28 in the Senate House of the University of London, Prof. E. C. Dodds, F.R.S., will give the opening addr 6 P.M. on the 28th. Other speakers will include I Neuberger and Dr. D. P. Cuthbertson. Further parti may be had from the secretary of the society, 56, Vi Street, S.W.1.

CORRIGENDUM: *Reduviid Bugs.*—Commenting on note of May 14 (p. 847), Dr. Petr Wygodzinsky, aut the Argentine monograph we were reviewing, points ou Chagas's disease is not transmitted by the bite of the tria but through their dejecta which are rubbed in the ey enter the skin through small wounds.

Appointments

ADAMS, J. C., M.D. Lond., F.R.C.S.: part-time orthopædic su St. Margaret's Hospital, Epping.

JUSTICE, J. J., M.B., B.SC. Glasg., D.P.M.: deputy medical su tendent, St. Mary's Hospital, Stannington.

MCNAB, G. R., M.D., B.SC. Edin., F.R.C.P.E.: physician sa [illegible] natorium.

[illegible] M.B. Lond., M.R.C.P., D.C.H.: con [illegible] h area.

[illegible] M.B. Dubl., F.R.C.S.E., D.O.M.S.: par Chase Farm Hospital, Enfield.

[illegible] Lond., M.R.C.P.: consultant phy Ipswich area.

ROBINSON, J. B., M.D. Lond., M.R.C.P.: chest physician, Hartlepool and southern part of Durham County.

WRIGHT, P. S., M.B. Birm., M.R.C.O.G.: asst. obstetrician gynæcologist, Oldchurch Hospital.

Colonial Service:

ANDERSON, N. E. W., M.B. St. And., D.P.H., D.T.M. & H.: director of medical services, Nigeria.

IN THE UNIVERSITY

RONIC œdema of the lower extremities occurring ut any apparent cause must be within the experi- of all general physicians and will probably have encountered by the majority of general practitioners.

ote et al. (1940) investigated 100 consecutive ients and 100 consecutive outpatients with varying es of œdema of both legs, and in 2, both of whom outpatients, no cause could be found. Of the ining 198 all but 4 were due to cardiac failure, renal se, obesity, varicose veins, hypoproteinæmia, myx- na, rheumatoid arthritis, bilateral femoral throm- , hepatic cirrhosis, postural causes, or lymphatic or us obstruction by malignant or leukæmic disease. other 4 were attributed to chronic lymphatic obstruc- resulting from recurrent overt lymphangitis and hadenitis associated with epidermophytosis.

the "Questions and Answers" column of one issue e *British Medical Journal* (1947) three practitioners aled for help in diagnosis and treatment of cases of nic bilateral œdema of the legs for which they could no adequate explanation. In the answer all were nosed as lymphœdema, and unnoticed attacks of hangitis, possibly due to epidermophytosis, were ulated as the cause of the lymphatic block. Lymph- ma is the usual label attached to such cases, and gh it may often if not always be a factually correct nosis it will be generally agreed that "chronic and plained œdema" would be a more honest description re there have been no antecedent inflammatory odes in the legs. It would be better if the term phœdema were reserved for cases in which there is a history or in which some cause for lymphatic mmation or obstruction is present.

erusal of the literature suggests that chronic and xplained œdema though not common is not excessively , and as nine such cases have recently been under our we thought it might be of value to record our rvations regarding their clinical features. The ression that we have gathered from the patients we have personally observed and from the numerous lications on the subject is that at least four types t.

CHRONIC HEREDITARY ŒDEMA

he first, most definite, and most widely recognised is chronic hereditary œdema or Milroy's disease, or Nonne-Meige-Milroy disease.

ttention was first called to the condition by Nonne 1) who described four cases occurring in two genera- s of a family and mentioned five near relatives who e similarly affected. In the next year Milroy pub- ed his well-known paper recording twenty-two cases rring in six generations of a family of ninety-seven roy 1892), and later he added two more to the cted members of this family and his follow-up hasised the benignity of the condition (Milroy 1928). ge (1899) described eight cases in four generations of amily, and Rolleston (1902) drew attention to the dition for the first time in the English literature. rding three cases in a family of eight. Since then pe and French (1907), McGuire and Zeek (1932), kes Weber and Schluter (1937a), Braham and Howells (1948), and numerous others have described further cases.

Either sex may be affected by this type of œdema which appears to be handed down as a mendelian dominant. The age of onset of œdema is variable: in twenty-one of the original twenty-two cases described by Milroy (1892) it commenced at birth, but in the majority of the other recorded cases it appeared at puberty. A few have commenced in early adult life and Ellis and Hall (1933) record two that developed during pregnancy.

Both legs are usually involved, but the œdema is sometimes not symmetrical and it may be confined to one limb. It commences round the ankle and lower calf and increases and extends proximally over a period of years after which it remains stationary. Usually the knee or Poupart's ligament are sharp upper limits for the œdema, but Richards (1931–32) has recorded an instance in which all extremities were involved and œdema of the face and hands occurred in one of the cases described by Ellis and Hall (1933). At first the œdema pits readily, but as years go by it gets firmer and pitting becomes less evident. The fact that the condition does not reduce longevity is stressed by all writers and Milroy's (1928) follow-up leaves no doubt on this point.

Drinker and Field (1933) produced artificial lymphatic obstruction in the legs of dogs and showed clearly that these animals were unduly prone to streptococcal infections in the œdematous limbs. This is probably the explanation of the "acute attacks" described by Hope and French (1907), McGuire and Zeek (1932), and Ellis and Hall (1933). These attacks, which tend to be recurrent, are always self-limiting and usually last about four days. They are characterised by increased swelling of the limb, and localised pain, redness, and tenderness, together with pyrexia and considerable constitutional upset. They have always developed long after the onset of the œdema. Apart from the occasional occurrence of such "acute attacks," the condition never causes any disability except for the weight and unsightliness of the affected limbs.

Opinion regarding the effect of pregnancy on this type of œdema varies. Hope and French (1907) state that it produces no alteration, but in a case recorded by Parkes Weber and Schluter (1937b) it was temporarily increased during each of five pregnancies, and as stated above two of Ellis and Hall's (1933) cases developed during pregnancy.

The œdema always subsides to some extent with rest and is aggravated by physical activity.

As regards treatment, the wearing of elastic stockings and sleeping with the foot of the bed raised are useful therapeutic procedures, but Kondoleon's operation has occasionally been carried out with some benefit. Thyroid, digitalis, and mercurial diuretics have often been tried, but none of them bring about any improvement.

The underlying abnormality causing the œdema in this hereditary group remains unknown. Many hypotheses have been put forward, and an attractive explanation postulates a congenital varicosity or other anomaly of the lymphatics. McGuire and Zeek (1932) examined biopsy and Kondoleon operation specimens from one of their cases but found no striking abnormalities apart from œdema and fibrosis. They found exactly similar changes in post-mortem specimens from cases of cardiac and other forms of œdema.

Two of our nine cases (nos. 8 and 9) belong to this group. In one (case 8) the leg swelling began to develop in middle life, which is unlike any other recorded case of hereditary œdema; but the fact that a brother was similarly affected suggests that the patient's œdema is of the true Milroy type. When she was first seen the œdema had been present for some years and pitted poorly: her hands were also involved to a lesser degree. A notable feature was the marked increase in her œdema which occurred in association with a general increase in body-weight during the year before she was seen. She has recently had an attack of erysipelas in one of her legs. The other patient (case 9) corresponds exactly to Milroy's description. The œdema was present at birth and when the child was seen by us at the age of ten there was no other physical abnormality and there had never been any disturbance of general health. Her paternal grandfather, now aged 65, and her paternal aunt, aged 40, have both had swollen legs since birth but neither has had any disability from this source, and both have led full and active lives.

CHRONIC ŒDEMA OF MILROY TYPE WITHOUT HEREDITARY ELEMENT

Rolleston (1902) in his paper refers to a woman of 24 with chronic œdema of the legs for which no explanation could be found and in which there was no hereditary element, and Parkes Weber said he had seen several such cases (Parkes Weber and Schluter 1937a). Homans (1933) terms them "sporadic non-filarial elephantiasis" and states that "acute attacks" never occur in this condition.

Three of our nine cases (nos. 1, 2, and 3) appear to belong to this group. All are females, and œdema commenced at 37 in case 1, 33 in case 2, and 17 in case 3. None of the previously recorded cases of chronic hereditary œdema appear to have commenced as late as the fourth decade. In each of our three cases the œdema is symmetrical and does not extend above the knee, but *case 2 had swelling of the arms and face for a period of* two weeks in 1946 and case 3 had swelling of the arms and face during a pregnancy which also produced a marked increase in the leg œdema. After delivery, however, the œdema of the face and arms subsided and that of the legs reverted to its usual mild degree. During the pregnancy there was no albuminuria, hypertension, or headache to suggest that toxæmia played any part in the aggravation of the œdema. In case 2 the œdema never disappeared after it first began to develop, but in case 1—a patient with a somewhat sedentary occupation—a most unusual feature was that a mountaineering holiday in Wales caused the œdema to disappear temporarily and a *walking holiday the next year also* produced considerable diminution in the swelling. In case 3, despite its long duration, the œdema has always been intermittent.

In two of the patients the subcutaneous tissues of the lower legs were tender and had a lobulated texture, and the skin of the anterior aspect particularly on the lateral side was reddened. In all three cases the œdema pitted fairly well. In none of the three was there any other relevant physical abnormality, and no family history of œdema, nor any personal or family history of allergy, could be obtained. *All the patients found that the* œdema was worse at the end of the day and less when they got up in the morning.

The duration of the œdema was 4 years in case 1, 13 years in case 2, and 22 years in case 3. All three patients are leading a full and normal life; one is a commercial artist and two are employed in a secretarial capacity.

With regard to treatment, two are wearing elastic stockings and sleeping with the foot of the bed raised, and these measures produce some improvement. The third case is not sufficiently severe to require treatment. 'Benadryl' was tried in two cases and 'Anthisan' in one, but neither produced any improvement. Thyroid was also given to one of the patients and mercurial diuretics to another, but these had no beneficial effect.

CHRONIC ŒDEMA ASSOCIATED WITH ALLERGY OR RESPONSE TO ANTI-HISTAMINE DRUGS

In two of the patients that we have observed
may be a factor in the causation of the œdema.
(case 4) was a woman who had suffered from asth
mittently throughout life and who also from time t
had pitting œdema of both ankles and lower
The œdema caused no disability and no cause for it
be found. It showed marked periodicity; there
no sign of it for several years and then it would
and persist for weeks or months. She has not
seen since anti-histamine drugs have been a
but on the one occasion when she sought advice re
her œdema it showed some response to ephedrine.

The second patient (case 5) is a woman, now
who had suffered from persistent œdema of the
face and hands for 16 years. She gave no person
family history of allergy but she suffered from
vasomotor flushing of her face and neck. Exhau
investigations revealed no cause for her œdema and
was given a course of T.A.B. injections as an emp
measure without benefit. When next seen she said
she had consulted another physician who had diag
"asthma of the blood" and prescribed benadryl, w
had produced striking and unequivocal improveme
her œdema though it had never completely disappe
This physician said that he had seen several similar
and it appears likely that a small number of ca
chronic and unexplained œdema are allergic in
and might appropriately be termed "a fixed typ
angioneurotic œdema."

Salvesen and Boe (1937) described a woman o
who had been a lifelong sufferer from asthma and
developed œdema of the legs, face, and back togeth
ascites and a right pleural effusion one year before
publication. No cause for this œdema could be found
it showed no response to thyroid, 'Salyrgan,'
vitamin B, or œstrin. They did not try ephedrine.

LIPŒDEMA

Allen and Hines (1940) described five cases of chr
œdema of the legs which they termed "lipeder
All the patients were female and had had generalised
symmetrical enlargement of the legs since girlhood. T
enlargement was due to an unusually large amount
fat in the buttocks, thighs, and legs; its causation
obscure but heredity seemed to play a part. Th
writers, quoting Youmans et al. (1934, 1935), suggest
the major factor in the production of œdema in su
cases is the excess of fat in the subcutaneous ti
of the legs, which produces a lack of tissue tone allowi
an excessive diffusion of fluid from the blood into th
extravascular spaces before the extravascular h
pressure rises sufficiently to prevent further loss of
from the capillaries. Pitting œdema was never
striking and was usually evident only towards the en
the day, particularly during hot weather and a
standing. Aching in the legs in the latter part of
day was a constant feature and the legs below the
were *sensitive to pressure and to pinching.* Allen
Hines (1940) pointed out that the condition did
reduce expectation of life or interfere with general hea
and the only treatment possible consisted in effort
reduce weight, massage, and the wearing of el
stockings.

Two of our cases (nos. 6 and 7) belong to this
Both *patients were females* and had had the cond
since adolescence. It had caused no inconveni
apart from the aching it produced in the latter
the day. One of them often had to retire to bed
or put her feet up on a chair in the evenings in
relieve this symptom, and while she was serving
the W.R.N.S. in the Middle East it became so distre
that she had to be invalided home. Both the pati

eriously distressed by the unattractive appearance r legs and there is no doubt that this as well as the led them to seek medical advice. Though there gross excess of subcutaneous fat in their calves highs, neither patient showed any evidence of lised obesity and no other members of their es had fat legs.

in the cases of Allen and Hines (1940), pitting a was never gross; it was always confined to the and lower calf and was usually evident only towards d of the day, especially when the weather was hot y had had to stand for long periods. Tenderness skin and subcutaneous tissues of the legs on pressure inching was a conspicuous feature, and both patients d redness and crazy-pavement-like scaliness of in on the anterior and lateral aspects of the lower

patient had two pregnancies without aggravation leg swelling.

wearing of elastic stockings and sleeping with the f the bed elevated were of some value in controlling ng in both cases; but neither massage nor thyroid ced any improvement, and anti-histamine drugs were tried in one case had no beneficial effect.

DISCUSSION

e tendency to describe all cases of chronic œdema hich no cause can be found as lymphœdema is to precated.

do not doubt that a proportion of such cases are to actual acquired lymphatic block, but in the ice of any history of lymphangitis or lymphadenitis, any possible provocative lesion such as epidermo-osis, and especially if the œdema is symmetrical, a mechanism seems unlikely, and the occurrence ansient or persistent œdema of hands and face in cases clearly indicates that all cannot be so ined. In none of the nine cases that we have observed there anything to suggest acquired lymphatic block. t then is the explanation of the œdema?

possible explanation of the lipœdematous group at these females develop during adolescence an ity which is localised to the lower extremities, and excess of subcutaneous fat in the legs produces static œdema as a result of lack of tissue tone. may be regarded as similar in nature to the cases neralised obesity in which leg œdema is so often seen. they should develop an excess of subcutaneous fat eir legs at adolescence is uncertain, but probably an inherited trait. That another, probably small, p of cases of chronic and unexplained œdema may llergic in origin seems likely, though we have not proved this to our own satisfaction. As regards nic hereditary œdema, the published cases leave no t that the cause lies in some inherited defect, gh the exact nature and site of this abnormality ins a matter for speculation; and why the œdema ld so often develop at puberty or later is difficult to rstand. It seems possible that the similar cases out any hereditary element have the same patho- as the Milroy type, for their manifestations are so much alike; but if this is so it is hard to explain tendency for the non-hereditary cases to develop in life.

rkes Weber and Schluter (1937b) published two of chronic œdema associated with hypertension. do not think that this comprises another group, for case was hypoproteinæmic and the other was clearly se of chronic hereditary œdema. The hypertension ars to have been purely coincidental.

l our patients found that their œdema was worse he end of the day, and was aggravated by standing and hot weather and improved by rest. Some also noted an increase in their swelling before menstruation. These features are not to be regarded as peculiar to the disorders we have described, for they are characteristic of all œdematous states. We can offer no explanation for the temporary improvement which occurred in case 1 apparently as a result of increased physical activity.

In two of our cases (nos. 3 and 4) the œdema was intermittent, but in all the others it was persistent; and after it had been present for some years it showed a tendency to become firmer and to pit less readily on pressure. This is thought to be due to fibrosis in the subcutaneous tissues and is not regarded as a characteristic of any particular group of cases but merely as the natural result of any chronic œdematous state. This fibrotic change gives the subcutaneous tissues a lobulated feel and makes them tender to pressure. The tenderness on pressure and pinching is particularly noticeable in cases of lipœdema, and this together with the aching in the legs which these patients experience suggests that the excess of fat may aggravate the tendency to fibrosis. It is in some ways reminiscent of Dercum's disease.

The tendency for the skin of the anterior and lateral aspects of the lower leg to become reddened and scaly, seen in our cases of lipœdema, was also present in some of our other cases and is probably an anoxæmic effect on the skin akin to varicose eczema and erythrocyanosis and not confined to lipœdema. A layer of œdematous tissue tends to insulate the skin from the warmth of the underlying vascular muscle.

We have little that is constructive to offer for the treatment of these cases. Elastic stockings and sleeping with the foot of the bed raised usually produces slight improvement. Massage seems to have so little effect that it is not worth the time and effort that it involves. Thyroid, digitalis, and mercurial diuretics are without any value, and it is doubtful whether Kondoleon's operation is ever justifiable in any of the four types of œdema that we have described, though in true obstructive lymphœdema it may occasionally produce real improvement. We believe that there is a group in which allergic mechanisms with histamine release may play a part, and anti-histamine drugs are always worth a trial, especially if there is an allergic background.

CASE DETAILS

Case 1.—Female, aged 41. Commercial artist. No significant previous illness and no personal or family history of allergy. No family history of œdema. Increasing painless symmetrical œdema of legs for four years, worse at the end of the day, after standing, in hot weather, and before and during menstruation. A mountaineering holiday in Wales in 1946 caused œdema to disappear for two weeks and a walking holiday in 1948 produced marked temporary diminution in swelling. Examination showed symmetrical below-knee œdema which pitted well. Skin of anterior and lateral aspects of lower legs reddened and scaly during winter months. Subcutaneous tissues in œdematous areas feel lobulated and are tender. No other physical abnormalities found. Urine free from albumin and sugar and no abnormality on microscopic examination of the spun deposit.

Radiography of the chest: no abnormality of the heart or lungs. Electrocardiogram: physiological. Blood-count: red cells 4,690,000; hæmoglobin 11·3 g. per 100 ml.; white cells 7500 with normal differential count. Blood chemistry: urea 33 mg., albumin 4·8 g., globulin 2·3 g., sodium 326 mg., chlorine ion 368 mg., and total cholesterol 265 mg. per 100 ml.

No response to thyroid, vitamin B_1, calcium, benadryl, or anthisan. Slight improvement with elastic stockings and sleeping with the foot of the bed raised.

Case 2.—Female, aged 46. Secretary. No personal or family history of allergy and no family history of œdema.

Partial thyroidectomy for thyrotoxicosis in 1938. Increasing bilateral painless symmetrical œdema of both legs since 1936. Arms and face swelled for two weeks in 1946. Leg swelling worse at the end of the day, but improved by rest. Examination showed firm symmetrical œdema below the knees on both legs which pitted only moderately well. Skin of lower legs reddened and subcutaneous tissues of lower legs lobulated and a little tender—quite unlike pretibial myxœdema (Trotter and Eden 1942). Exophthalmos still present but no other evidence of thyrotoxicosis or other physical abnormality. Urine free from albumin and sugar and no formed elements microscopically.

Radiography of heart and lungs: no abnormalities. Radiography of legs: trabeculated subcutaneous soft tissue swelling but normal bones. Electrocardiogram: physiological. Blood-count: red cells 5,110,000; Hb 14·1 g. per 100 ml.; white cells 9100 with normal differential count. Basal metabolic rate + 24%. Wassermann reaction—negative. Blood chemistry: urea 25 mg., albumin 3·9 g., globulin 2·3 g., sodium 330 mg., and total cholesterol 246 mg. per 100 ml.

No response to benadryl or mercurial diuretics. Slight improvement with elastic stockings and sleeping with the foot of the bed elevated.

Case 3.—Female, aged 39. Secretary. No personal or family history of allergy. No family history of œdema. No significant previous illness. Bilateral ankle œdema for a few days about twelve times a year since the age of 17. During pregnancy in 1946 ankles, face, and arms became persistently swollen; swelling disappeared after delivery, and leg œdema reverted to its previous state. Examination showed slight œdema of both ankles which pitted well. Urine specific gravity 1020. No albumin or sugar and no microscopic abnormality.

Urea-concentration test 2·3%, 3·0%, and 3·0%. Blood-count: red cells 4,000,000; Hb 10·8 g. per 100 ml.; white cells 8950 with normal differential count. Blood chemistry: urea 33 mg., albumin 4·2 g., globulin 2·2 g., cholesterol 287 mg., sodium 326 mg., chlorine ion 373 mg., calcium 11 mg., and potassium 20·5 mg. per 100 ml.; alkaline phosphatase 3·5 units. Liver-function tests normal. Œdema not sufficiently severe to require treatment.

Case 4.—Female, aged 46. Housewife. Lifelong history of intermittent asthma. No other significant illness. No family history of œdema. Painless symmetrical ankle œdema for periods of weeks or months throughout life. Apart from moderate œdema of ankles and lower calves which pitted well, no physical abnormality. Urine free from albumin and sugar and no microscopic abnormality. On the one occasion when she sought advice on account of her œdema it gradually disappeared with ephedrine gr. $^1/_2$ t.d.s.

Case 5.—Female, aged 38. Housewife. No family history of œdema. No personal or family history of allergy. Œdema of right leg since 1933 disappeared for a year after a pregnancy in 1935. Left leg became swollen in 1936 and hands and face in 1937. All swelling disappeared for six months after pneumonia in 1942. Œdema worse at the end of the day and before menstruation; goes down a little during the night. Examination showed marked vasomotor flushing of face and neck, firm symmetrical œdema of both legs which pitted poorly, and œdema of wrists, face, and conjunctivæ. No other physical abnormality. Urine free from albumin and sugar; specific gravity 1015. No microscopic abnormality in the spun deposit.

Radiography of heart and lungs showed no abnormality; neither did a skull X ray. Basal metabolic rate + 10%. Blood-count: red cells 4,740,000; Hb 13·3 g. per 100 ml.; white cells 10,850 with normal differential count. Blood chemistry: urea 40 mg., albumin 4·0 g., globulin 2·8 g., total cholesterol 275 mg., sodium 300 mg., chlorine ion 371 mg., and potassium 23·5 mg. per 100 ml. Urea-concentration test 3·5%, 2·9%, and 1·6%. 17-keto-steroids 1·2 mg. in 24 hours. Erythrocyte-sedimentation rate 20 mm. at 1 hour (Wintrobe).

No response to mercurial diuretics, salt-free diet and restricted fluids, or to T.A.B. injections. Marked response to benadryl.

Case 6.—Female, aged 34. Housewife. No personal or family history of allergy. No family history of œdema or of fat legs. Very fat calves and thighs aching and becoming œdematous round the ankles towards the end of the since puberty. Hot weather and standing aggravate swelling and pain. Examination showed gross inc subcutaneous fat of calves and thighs which were and felt lobulated. Pitting œdema round the ankles in evenings. Skin of anterior and lateral aspect of lower reddened and scaly. No generalised obesity and no physical abnormality.

Urine normal. No increase in leg swelling during pregnancies. No response to thyroid. Elastic b controlled swelling to some extent.

Case 7.—Female, aged 38. Secretary. Eczema asthma as a child. No other significant illness. M had eczema and a brother has hay-fever. No family of œdema. Since the age of 17 has had fat legs with and ankle œdema towards the end of the day, es if she stands a lot and in hot weather. When serv the W.R.N.S. in Middle East aching and swelling so that she had to be invalided home. Often has to go to early or sit with feet on a chair in the evenings of the aching. Examination showed gross excess of cutaneous fat in calves and thighs which was tende pressure and felt lobulated. Moderate pitting œdema ankles at the end of the day. Skin of lower legs red "crazy pavement" scales on anterior and lateral No other physical abnormality. Not generally obese. free from albumin and sugar and no microscopic abno

Radiography of heart, lungs, and legs normal. E cardiogram: physiological. Basal metabolic rate – Urine-concentration test 1005, 1010, 1025. Blood-cou red cells 4,080,000; Hb 11·8 g. per 100 ml.; white 5300 with normal differential count. Erythrocyte-sed tation rate 6 mm. at 1 hour (Wintrobe). Blood chem urea 27 mg., uric acid 2·8 mg., creatinine 1·8 mg., alb 4·0 g., globulin 1·6 g., total cholesterol 297 mg., 337 mg., chlorine ion 375 mg., calcium 11·8 mg., and phorus 2·3 mg. per 100 ml., alkaline phosphatase 3·2 Liver-function tests normal.

No response to anthisan, benadryl, thyroid, or ma Elastic stockings and sleeping with the foot of the bed produced slight benefit.

Case 8.—Female, aged 48. No personal or family hi of allergy. Venous thrombosis of left leg in 1929 follo a blow from a tennis racquet. Always suffered from hypersensitivity and a tendency to chilblains on the Menopause at 42. For some years increasing painless metrical œdema of legs which had been markedly wors the past year in which she had put on much weight. Lat the hands have also been swollen to a lesser degree. swelling worse at the end of the day and reduced by re bency. Recent attack of erysipelas in one leg. Examin showed symmetrical œdema of both legs which pitted and did not extend over the knees. The hands were swo but no pitting was evident. Physical examination wa otherwise negative. The urine was free from albumin and sugar.

Wears elastic stockings with slight benefit. A brother is similarly affected but no other family history was obtainable

Case 9.—Female, aged 10. No personal or family hist of allergy. Paternal grandfather now aged 65 and pat aunt now aged 40 have had swollen legs without disturb of general health since birth. Patient's legs were s at birth and have remained so since. Worse at the end the day and in hot weather. Go down a little during night. Never any œdema of any other part of the No other symptoms, never any illness. Physical examin revealed bilateral symmetrical œdema of the legs exten to just below the knees. Marked pitting; no skin cha and no tenderness or lobulation of subcutaneous tis Heart, abdomen, and urine normal and no other phy abnormality.

Had had much massage which produced slight but tra improvement.

SUMMARY

Nine cases of bilateral œdema of the legs not due any of the common causes are reported and discussed.

We are indebted to Prof. P. C. P. Cloake for refe case 9 to us.

HE prognosis of anuric uræmia can be improved by treatment outlined below. For the past two years have investigated this type of uræmia and studied 30 patients with more than four days' anuria each. ur interest was originally stimulated by the develop- t by Kolff of an artificial kidney (Kolff and Berk), and in the early stages the accent was on the oval of retained substances after the full clinical ure of uræmia had appeared (Bywaters and Joekes , Joekes and Bull 1948). More recently, as a lopment of the dietetic control method of Borst 8) and its combination with the control of water nce as advocated by Lattimer (1945) and others, have tried to prevent the development of the classical ical picture of uræmia.

CLASSIFICATION

roadly speaking, there are two types of uræmia m the therapeutic point of view: one in which the ney can excrete water but cannot maintain a normal *ieu intérieur* without special management; the other which negligible quantities of water are excreted. s this latter group, the anuric uræmias, with which are primarily concerned, and its particular importance that a large proportion of patients may recover pletely.

TREATMENT

resented with a case of anuria, one should first lude any obstruction which is distal to the renal vis and needs surgical intervention. Secondly, factors side the kidney, such as general circulatory distur- ces and alkalosis, which themselves may produce al failure, should be recognised and, if possible, ected. All other cases, including those which have responded to the correction of extrarenal factors, treated along the lines indicated below.

PROGNOSIS

ecovery to a level of renal function adequate for health be expected in the following groups.

(1) *Lower-nephron nephrosis*, including the types following mismatched blood-transfusion, crush syndrome, intravascular hæmolysis from various causes, post-abortion anuria, and the lesion following protracted "shock."

(2) *Toxic nephrosis*, including poisoning by mercury, carbon tetrachloride, phenol, &c.

(3) *Acute Nephritis.*—Complete recovery is possible in acute nephritis even where there is protracted oliguria or anuria with gross retention of nitrogen. Probably the mortality in the acute phase can be lessened if the patient can be tided over the oliguric period.

Recovery to a previous level of renal function may take place in any chronic renal lesion after an acute episode precipitated by infection of the urinary tract, exacerbation of the underlying lesion, or extrarenal causes.

Death may be expected in an anuric episode in a patient with malignant hypertension, bilateral cortical necrosis of the kidney, and Lohlein's stormy subacute nephritis. A patient with chronic nephritis which has steadily deteriorated to severe oliguria will also not recover.

PRINCIPLES OF TREATMENT

The pathogenesis of the various symptoms and signs of uræmia have been adequately dealt with by Harrison and Mason (1937) and Bradley (1948). From a study of our patients with anuric uræmia we have evidence to suggest that, at least in this condition, the following factors are the most important: Disturbances of water balance, disturbances of mineral balance, and disturbances of nitrogen balance.

Water Balance.—It has been suggested that water overload might play a part in the pathogenesis of uræmia. Many workers, including Lattimer (1945), Kugel (1947), Humphrey and Jones (1947), Thorn (1948), Coller et al. (1948), and Muirhead et al. (1948), have appreciated the importance of water balance, and Lattimer (1945) reviewing the treatment of 33 cases of urinary suppression, found that of patients given less than 2000 ml. of fluids a day none died, whereas of those given 3500 ml. or more 75% died. He sums up: "the body is not analogous to a tank into which water can be forced until it finally bursts out through the kidneys." Our own experience is in direct accord with this view. We have not seen a patient with anuric uræmia dying in under fourteen days who has not shown in life signs of water overload and at necropsy evidence of gross pulmonary or cerebral œdema. In anuric patients, in the absence of vomiting, water loss is limited to extrarenal routes—i.e., lungs, skin, and fæces. Under normal conditions this loss is 600–1000 ml. a day. We accordingly limit the fluid intake in anuric patients to 1000 ml. a day. Any vomiting must be dealt with as indicated below.

Mineral Balance.—Though electrolyte disturbances are significant, we consider that disturbances of water balance are of much greater importance. In the absence of diarrhœa and vomiting the body has no effective pathway for electrolyte excretion other than the kidney, and administration of electrolytes in anuria may lead to gross disturbances of electrolyte balance. Excess of potassium may cause sudden death from cardiac arrest (Hoff et al. 1941, Finch et al. 1946), and excess of sodium is probably harmful in other ways. We are uncertain of the importance of excess or deficiency of chloride and bicarbonate but find it impossible to correct anion deficiency without at the same time introducing excessive quantities of cation. All our cases of protracted anuria have had considerable disturbances of chloride and bicarbonate balance, but this has not prevented the onset of diuresis. For this reason our diet is electrolyte-free until diuresis starts, and no attempt is made, while

the patient is still anuric, to correct the electrolyte disturbances. During the diuresis accompanying recovery electrolyte loss may be considerable and must be replaced quantitatively.

Nitrogen Metabolism.—The end-products of protein katabolism other than urea are possibly toxic (Harrison and Mason 1937, Bradley 1946). Further, accompanying the breakdown of tissue and most protein-containing foods, potassium and possibly other toxic substances are liberated. For these reasons it is desirable to depress endogenous and exogenous nitrogen metabolism as far as possible. It has long been known that a high carbohydrate intake depresses endogenous nitrogen metabolism, and Borst (1948) has developed a diet for use in uræmia which takes advantage of this fact. The diet is nauseating by mouth, and we have found that it further increases the vomiting to which uræmic patients are liable. Borst has had excellent results in his Dutch patients, but in British patients, with the foodstuffs at present available here, we have been unable to exceed an intake of 1000 calories a day, and not infrequently the greatest possible intake has been 500 calories a day. For these reasons we have fed our patients through a permanently indwelling stomach-tube and have given 400 g. of glucose and 100 g. of fat a day in this way. This 2500-calorie protein-free and mineral-free diet can be taken with little discomfort for periods of up to three weeks.

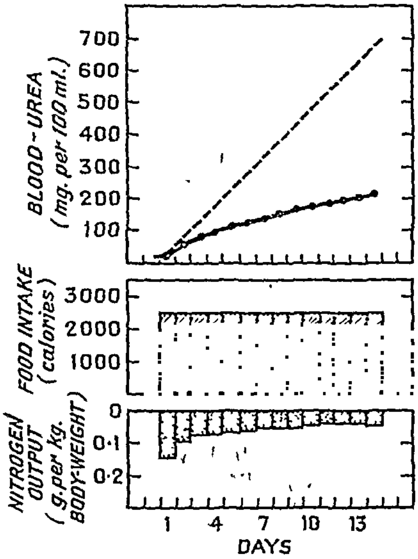

Fig. 1—Mean data on nitrogen metabolism in 5 controls: dotted line, usual rate of rise of blood-urea level in anuric patients not on régime; continuous line, rate at which blood-urea level would rise in anuric patients on régime, calculated by assuming retention of daily urinary nitrogen output.

SUMMARISED PROCEDURE

On admission of the patient to hospital a stomach-tube is passed through the nose. (Plastic tubes 2–3 mm. in diameter and without a bulbous tip have the advantages over the ordinary Ryle's tube that they are less irritating in the nasopharynx, are easier to pass, and, because of their slightly greater rigidity, are much more difficult to vomit out.) Through this tube the following mixture is dripped at a steady rate throughout the twenty-four hours:

Glucose ..	400 g.
Peanut oil ..	100 g.

Acacia q.s. to emulsify.
(Vitamins optional.)
Water to 1 litre.

All vomit is collected, filtered through lint and returned to the stomach in the same way. This ensures that the fluid intake is accurate, that there is no loss of food by vomiting, and that no loss of electrolytes occurs through vomiting. Serious disturbances of electrolyte balance during the anuric phase may be readily avoided by this régime.

By contrast, however, when diuresis starts, it with it special difficulties in management, beca electrolyte-regulating function of the kidney r slowly. Urinary losses of the various electrolytes be made good quantitatively, and, to the basic of 1 litre of water, fluid is added daily in a volume to the urine passed during the preceding twenty hours. It is desirable that the drip feeding shoul discontinued and superseded by a low-protein diet the urine output exceeds 1 litre a day.

Because anæmia is known to lead to diminished function, fresh packed red cells are transfused if hæmoglobin concentration is below 70%.

EFFECT OF RÉGIME

The effect of this régime has been examined in classes of patient: (1) controls with duodenal in whom there was no evidence of renal diseas disturbance of nitrogen metabolism; (2) patients reduced renal function but without anuria; and patients with anuric uræmia. Information on nitrogen, mineral, and water metabolism of t patients was obtained, and certain of the data presented. A detailed report will be published elsew

Controls without Renal Disease

Fig. 1 shows mean data on the nitrogen metab in 5 controls. The amount of urea excreted daily determined, and the total volume of body water in patient estimated from the body-weight. The ri concentration of urea in the body water resulting the addition to it of the daily urea output gives an mate of the height to which the blood-urea level rise if the patient had been anuric (Borst 1948).

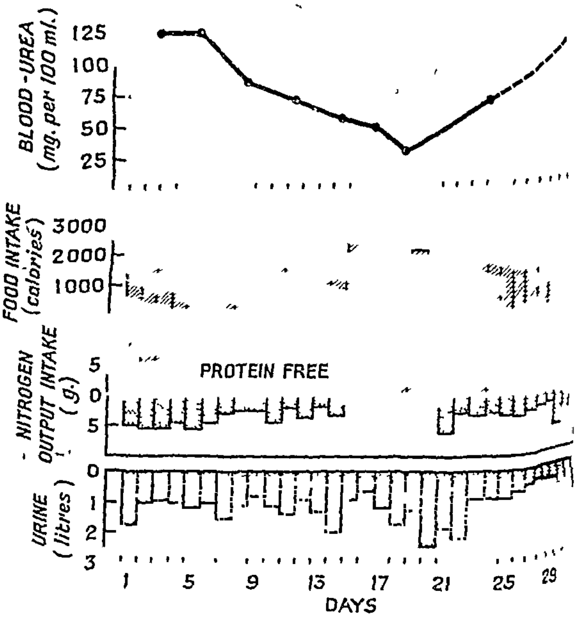

Fig. 2—Nitrogen metabolism in malignant hypertension: not rapid fall of blood-urea level on protein-free high-calorie and (2) its subsequent rise when 10 g. of protein containing 14. N_2 was given.

There was a rapid reduction of endogenous ni metabolism, as indicated by the steady diminu urea-nitrogen excretion to about 0·04 g. per kg body-weight a day. If these patients had been their blood-urea levels would have risen as slowly 17·7 mg. per 100 ml. a day during the first week 10·1 mg. per 100 ml. a day during the second In anuric patients not on this régime we have

erage daily rise of blood-urea level to be about . per 100 ml.

ic Renal Disease

example is shown in fig. 2. It will be seen that, n the presence of very severe renal damage, some ion in blood-urea can be achieved. The patient data are presented in fig. 2 had malignant hyper-n and such reduction of renal function that he d an increasing azotæmia on a diet containing 0 g. of protein a day (see day 15 onwards in the). He died about a month after the end of the charted, with a blood-urea level of over 400 mg. 0 ml., and at necropsy the diagnosis of malignant tension with gross renal damage was confirmed.

ic Uræmia

ring the six-month period ending ecember, 1948, we treated 11 its with extreme oliguria or a lasting 7–21 days. Data on patients are presented in the mpanying table.

the 11 patients 4 died. Of these, 8 and 9 were admitted comatose, t ventricular failure with gross na, and died within twenty-four of admission without regaining iousness. Case 6 was admitted on ighth day of anuria, having had arotomy and splanchnic block previous day. On the day r admission he developed eral basal pneumonia and burst abdominal wound, and he tually died of these compli-ns on the fourteenth day after nset of anuria, when his renal ion was improving. Case 2 arly died after the start of sis. The cause of death was ably a cerebral abscess.

e other 7 patients survived left hospital symptom-free and adequate renal function. In no did extreme oliguria or anuria for less than seven days, and it remarkable that case 10 did not ve an effective urinary output the twenty-fourth day. By tive urinary output we mean re of urine a day, because the at this stage is of practically same composition as plasma filtrate, and at a high level of blood-urea 1 litre is needed on an average to rid the body of a single day's breakdown products of endogenous protein. This is further borne out by the fact that the start of the fall of the blood-urea level almost always coincided with the day on which the diuresis reached 1 litre. The severity of the cases may further be judged by the fact that 3 out of the 7 surviving patients were referred to us by physicians who regarded the prognosis as hopeless.

The effectiveness of the diet as regards its nitrogen-sparing effect is evident from the data presented. In every case there was a considerable slowing of the rate of rise of the blood-urea level after the régime had been instituted. After the same duration of anuria, or at

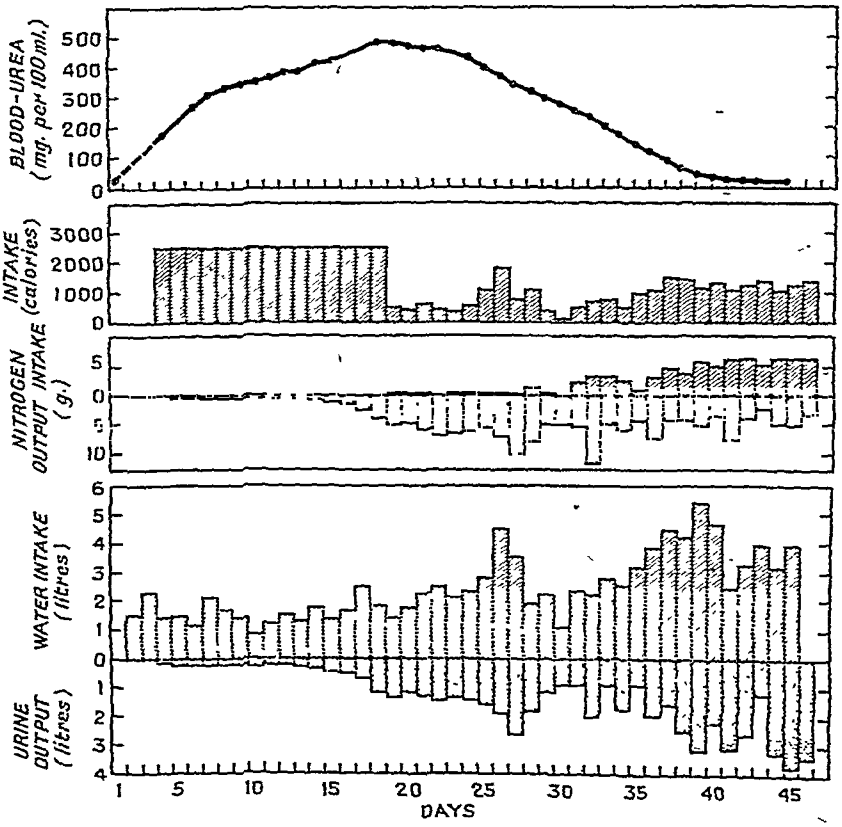

Fig. 3—Nitrogen metabolism in lower-nephron nephrosis (case 5): note excessive fluid intake on day 26 (this was immediately followed by coma, and the resulting disturbance of water and electrolyte balance only passed off on the 32nd day).

the same level of blood-urea, these patients were in very much better general condition than that we had been accustomed to see in patients not on the régime. Often they were sufficiently alert to take an interest in reading or sewing, despite long periods of anuria. This improvement we attribute to effects of the régime other than those on the nitrogen metabolism.

It is of interest that, when feeding by mouth was started again, it was impossible to maintain a high calorie intake, and in some cases it was difficult to maintain a sufficiently high fluid intake as well. This happened despite the fact that the diet contained protein and was not unpalatable, and it emphasises the superiority of tube feeding over feeding by mouth in these cases.

ILLUSTRATIVE CASE-RECORDS

Case 2.—A woman, aged 32, had had a severe hæmorrhage from a septic incomplete abortion on July 9, 1948, and been transfused with 1 pint of incompatible blood. Anuria and jaundice had come on within a few hours. The patient was transferred to Hammersmith Hospital on the fourth day of anuria.

On admission she was anæmic and slightly jaundiced. There was no evidence of water imbalance, but there were signs of a septic incomplete abortion. Her temperature was 99°F.

Course.—The régime was started immediately. The patient's temperature remained slightly raised. On the seventh day she was treated with the artificial kidney. On the eighth day a blood-culture grew *Staph. aureus,* and her temperature had risen. By the tenth day her temperature had risen still further and was swinging in type. She became severely ill, and on the twelfth day she began to have fits. At this stage her temperature started to respond to penicillin and streptomycin, which had been given throughout. The volume of urine began to increase on the fifteenth day, but the patient continued to have fits with increasing frequency and died on the eighteenth day.

Blood-urea Levels.—The mean rise before the régime was instituted was 60 mg. per 100 ml. a day; on the régime before dialysis 25 mg. per 100 ml. a day; and after dialysis but with fever 31 mg. per 100 ml. a day.

Necropsy Findings.—Pigment nephrosis. The uterus showed signs of recent abortion. There was a cerebral abscess due to a penicillin-resistant staphylococcus.

Case 5.—A woman, aged 24, had given herself on Aug. 28, 1948, when about three months pregnant, an intra-uterine douche of soapy water. Shock had developed rapidly, and she had been admitted to hospital. She had remained shocked for about six hours. About eight hours after the douche she had passed a fourteen-week fœtus. Anuria had been noted from the outset, and jaundice from the next day. She was transferred to Hammersmith Hospital on the fourth day of anuria.

On admission there was no clinical evidence of water imbalance and no jaundice. The patient was tender in the iliac fossæ, and her uterus was enlarged to two finger breadths below the umbilicus.

Course.—The régime was started immediately. Diuresis began on the fourteenth day, slowly increasing to exceed 1 litre on the eighteenth day. During the week succeeding the onset of the diuretic phase, gross symptoms and signs, including coma, developed which were believed to be due to disturbances of water and electrolyte balance. However, when these difficulties had been overcome, the patient made a good recovery (fig. 3).

Blood-urea Levels.—The mean rise before the régime was instituted was 57 mg. per 100 ml. a day; during the first week on the régime 26 mg. per 100 ml. a day; and during the week on the régime 16 mg. per 100 ml. a day.

Diagnosis.—Lower-nephron nephrosis due to intra hæmolysis caused by soap.

Case 6.—A man, aged 47, with a doubtful previous mental abnormality, had developed ab colic, vomiting, and severe diarrhœa on Sept. 30, It was not known for certain whether he had been from the outset, but two days later, on his a hospital, this had been definite. Fluids had been a tered in large quantities, and on Oct. 8 a laparotom splanchnic block had been done. The patient was to Hammersmith Hospital on Oct. 9.

On admission he was grossly overhydrated, as sh œdema. His blood-pressure was 230/118 mm. Hg.

Course.—The régime was started immediately. C dation was noted at both lung bases on Oct. 10, temperature rose. Penicillin was given. On Oct. 12, coughing, the patient ruptured his abdominal wound. D began on Oct. 11, but he died on Oct. 15, which was pr the thirteenth day of his illness.

Necropsy Findings.—Bilateral lower-lobe laparotomy wound; and lower-nephron nephrosis of un cause.

Case 8.—A female, aged 20, had had an abortion on or about Oct. 18, 1948. On Oct. 20 she had been to a fever hospital with signs of incomplete generalised peritonitis, and sepsis of the genital tract *welchii* had been grown from the uterus, and large do penicillin and sulphonamides had been given. Severe o and uræmia had been noted within two days of her to hospital. She had developed paralytic ileus, coma, purpura, and been transferred to Hammersmith H on Oct. 29.

On admission she was comatose, febrile, and very tous, and her skin had numerous purpuric spots and moses. Her blood-urea was 520 mg. per 100 ml. She four hours after admission.

Necropsy Findings.—Pigment nephrosis and lo pelvic peritonitis.

Case 9.—A man, aged 25, had had an attack of of unknown cause in November, 1944. From December,

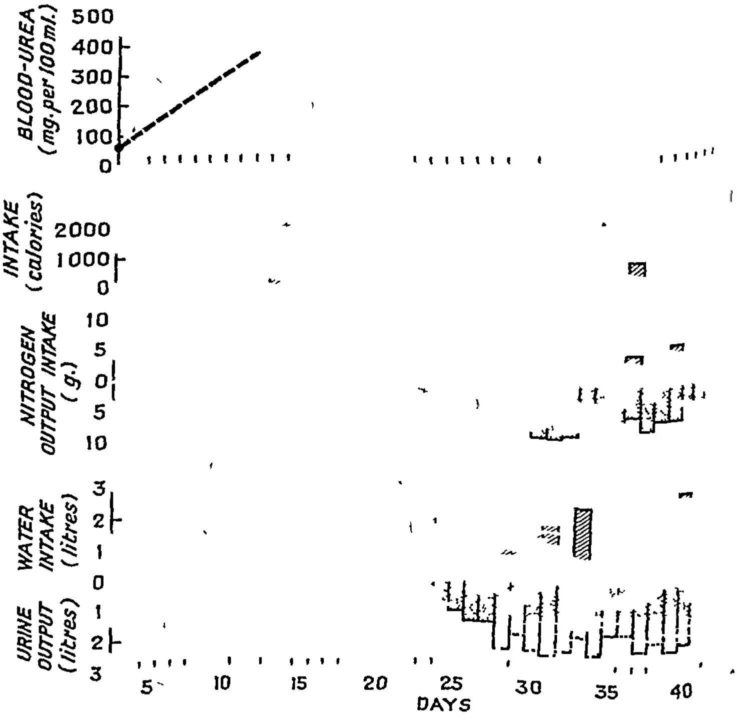

Fig. 4—Nitrogen metabolism in lower-nephron nephrosis (case 10): note long period of oliguria; urine output of 1 litre was only reached on 25th day

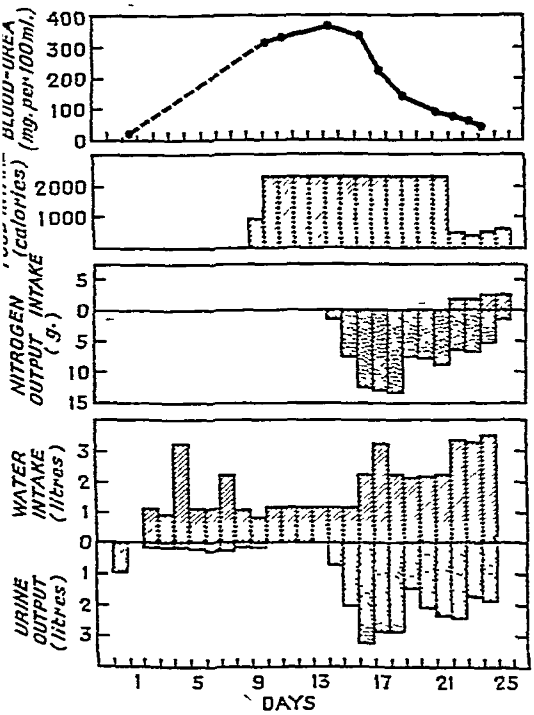

5—Nitrogen metabolism in lower-nephron nephrosis (case 11): te unusually rapid fall in blood-urea level after start of uresis.

ιad had frequent hæmatemeses requiring blood-transfu-s. In November, 1948, he had been admitted to hospital ı the clinical picture of Banti's syndrome, and on Nov. 8 ortacaval anastomosis had been made. The operation lasted six hours, and during its course 2 pints of incompatible blood had been transfused. The patient been treated with large quantities of intravenous fluids, peritoneal dialysis had been done from the third day ards. On the fifth day he had become comatose, and the eighth day he was transferred to Hammersmith spital.

n admission he was comatose, pale, grossly œdematous. jaundiced, and had a venous pressure 4 cm. above the nal angle. His blood-pressure was 150/60 mm. Hg.

ourse.—On the evening of the eighth day the patient treated on the artificial kidney, but after ten hours ing which time 26 litres of blood had been dialysed, he eloped a gastro-intestinal hæmorrhage and died without aining consciousness. It was of interest that the gross ema was removed by the dialysis.

ecropsy Findings.—Old and almost complete obliteration the portal vein near the liver hilum; extensive collateral ulation; recent portacaval anastomosis: and pigment hrosis.

ase 10.—A woman, aged 27, had given herself on Nov. 23, 8, when she was about two months pregnant, an intra-ine douche of 'Dettol' and soap, and had aborted next ning. Severe oliguria had probably started immediately, this is not certain from the history. On the eighth day patient had been admitted to another hospital, and on eleventh day she was transferred to Hammersmith spital.

n examination she was somewhat drowsy, but there e no other signs or symptoms of uræmia. There was evidence of water imbalance.

ourse (fig. 4).—Diuresis was considerably delayed, starting the twenty-first day and only exceeding 1 litre on the nty-fifth day. However, her general condition did not eriorate until the twenty-seventh day, during the diuretic se, when she had an epileptic fit. Otherwise her progress smooth.

lood-urea Levels.—The rise before the régime was instituted 35·3 mg. per 100 ml. a day, and on the régime 8·5 mg. 100 ml. a day.

Diagnosis.—Severe lower-nephron nephrosis following abortion.

Case 11.—A girl, aged 16, had attempted to procure abortion by syringing on Nov. 30, 1948. Some hæmorrhage had followed, and she had been shocked for about twenty-four hours. The fœtus had been passed a few hours after the syringing. There had been severe oliguria from the outset. Despite penicillin given from the first day, the patient had developed uterine sepsis, and the uterus had been evacuated on the third day. The patient had become drowsy and œdematous, with profuse diarrhœa and vomiting, and had been extremely ill. The penicillin dosage had been increased on the seventh day, and the patient was transferred to Hammersmith Hospital on the ninth day, by which time her temperature was settling.

On admission the patient was œdematous, drowsy, and pale (Hb 44%). Her peripheries were warm, with a bounding pulse, and capillary pulsations in the fingers. Her plantar reflexes were extensor. Her uterus was palpable and tender, and there was tenderness in the iliac fossæ.

Course (fig. 5).—The régime was started immediately. The temperature settled rapidly and within two days was normal. After a profuse epistaxis on the thirteenth day the patient was transfused with 2 pints of blood. Diuresis started on the fourteenth day, and the further course was uneventful except for unexplained pyrexia in the fourth and fifth weeks. Improvement was unusually rapid.

Blood-urea Levels.—The rise before the régime was instituted was 35 mg. per 100 ml. a day, and on the régime 12 mg. per 100 ml. a day.

Diagnosis.—Lower-nephron nephrosis following abortion.

DISCUSSION

From a study of published reports it is impossible to gain an accurate figure for the mortality in lower-nephron nephrosis, but we cite the following estimates as an indication: Lucke (1946) estimated the mortality to be 90%; and Kilduffe and DeBakey (1942) found the mortality of all hæmolytic reactions regardless of severity, occurring in a series of 43,284 blood-transfusions to be 57·7%. Both Lucke's and Kilduffe and DeBakey's mortality figures are an over-all survey, whereas we have only included patients whose anuria had lasted for more than a week. In such a series an even higher mortality might be expected. We believe that, with the régime outlined, the mortality should be negligible.

We have evidence that the high carbohydrate content of this diet is important not only in reducing the breakdown of endogenous protein but also in reducing the concentration of potassium in the extracellular fluids. We wish to emphasise again that the effectiveness of the régime is not entirely due to its nitrogen-sparing effect, but that collateral effects on mineral balance are of equal or greater importance.

Dialysis methods have their dangers and difficulties, and we believe that, where this régime is started early, dialysis should not be undertaken. However, dialysis probably has a place in the treatment of the patient who is already in gross water, mineral, and nitrogen imbalance. Other methods of therapy, such as splanchnic block, spinal anæsthesia, and decapsulation of the kidney, are of doubtful value, and their use must be assessed against conservative management.

SUMMARY

A régime for the treatment of anuric uræmia is described which is based on accurate control of water, mineral, and nitrogen balance.

During the anuric phase the fluid intake balances the insensible water loss. The diet is completely nitrogen-free and mineral-free and high in calories to depress endogenous nitrogen metabolism. To ensure an adequate and accurate intake of water and calories, a mixture of fat and glucose in water is given by intragastric drip.

During the phase of "recovery-diuresis" the management is modified to replace the urinary loss of water and minerals.

If the conservative management is instituted sufficiently early without previous overhydration, diuresis can be confidently anticipated in anuria due to any recoverable renal lesion. The recovery may be considerably delayed, and in one of our patients it took place after more than three weeks' extreme oliguria.

We wish to thank the sisters and staff of wards B 1, 2, 3, and 4, and Miss Simmonds and her staff in the dietetic department, for their patience and willing cooperation; Miss Patricia Burrows for assistance with the diagrams; the staff of the biochemical department for certain analyses; and Professor McMichael for his help throughout.

REMOVAL OF SIMPLE UNIVESICULAR PULMONARY HYDATID CYST

N. R. BARRETT
M.Chir. Camb., F.R.C.S.
SURGEON TO ST. THOMAS'S HOSPITAL, LONDON

MY experience of pulmonary hydatid disease (now comprising nearly 50 cases) has led me to express some opinions on the pathology, diagnosis, and treatment of this condition.[1] As the cases have accumulated ideas have matured; and a technique for removing the parasite from the lung has been gradually evolved. The object of this communication is to report the details of this part of the operation.

In the treatment of a hydatid cyst in the lung three things must be achieved: to remove the parasite, to avoid contaminating the pleural cavity or the wound with hydatid fluid, and to deal with the "empty sac" in the lung. The most difficult of these is to get the cyst out of the body without spilling a drop of hydatid fluid, and the only way of achieving this is to remove it intact without tearing, puncturing, or rupturing the laminated membrane.

Circumstances are more favourable to the surgeon in the case of lung cysts than when the parasite is lodged in other organs. The reason is as follows. In the ordinary course of events if a hydatid in the lung is treated expectantly it grows until some complication occurs or the host dies. As the cyst wall approaches the surface of the lobe which contains it, the adventitia thins out, in the area where the laminated membrane abuts on the visceral pleura, until finally it cracks and the parasite is extruded spontaneously from the lung into the pleura. In this process the hydatid sometimes ruptures, but it often remains intact and falls to the bottom of the pleural cavity, where it gains a new attachment to the host and continues to grow. tendency to herniate out of the lung naturally is imita in the operation to be described. The laminated m brane is strong so long as it is intact, but a ne however fine, introduced into the cyst for aspiratin dry at operation, practically always starts a tear w results in rupture of the cyst before the parasite can got out of the body. If the cyst leaks or ruptures i difficult to pack it off so as to prevent contaminatio the tissues with scolices or brood capsules.

TECHNIQUE

A technique which offers good hope of success in case of univesicular simple hydatid cyst is as follows

The patient is given a general anæsthetic, and this is ma tained after a cuff tube has been introduced into the trac to make an airtight circuit. The head of the table is lo so that if the cyst ruptures into the bronchus the h drains from the lungs by gravity. The appropriate he thorax is opened, either by rib-resection or an interco incision placed at about the level of the middle of the c and the pleural cavity is opened *widely* with rib spreaders. pleural adhesions are present they are divided so that lobe which contains the cyst is free. The affected lobe, where a giant cyst is present, the cyst, is then enclosed i bag of thin mackintosh, made like a sponge bag, with stri at the top for gathering up the inlet, but the bottom open. The bag is placed round the lobe containing cyst with the strings at the hilum, and these are dr up moderately tightly to encircle the neck of the lobe with impeding respiration in the lobe or the blood-supply. bottom of the bag is then opened out, brought through incision and spread out on the surface of the wound so t the affected part is inside a waterproof container. The not only gives some protection against accidental rupt but, later in the operation, is an excellent retractor. exact position of the cyst in the lobe is now ascertai and in most cases the adventitia will be seen on the surf of the lung as a patch of white membrane. If the hyda has not grown up to the surface, the lung is incised over cyst and down to the adventitia. The stage is now set *removing the cyst.*

The adventitia is partially incised by a straight cut wit knife. The length of the incision should be about the sa as the diameter of the cyst measured in the radiographs, a it should be placed towards the bottom of the cyst as t patient lies on the table. The incision must be ma cautiously, because as a rule the adventitia of lung cysts not more than $^{1}/_{8}$ in. thick. The object is to form a cra in the adventitia and not to expose the laminated membra throughout the length of the incision. If the laminated mem brane is exposed it will be obvious because of its colour white faintly tinged with blue. Once the laminated membra has been exposed in one spot the incision in the adventitia can be extended by lifting it off the cyst and cutting wit blunt-pointed scissors for about an inch. No attempt shoul be made to expose the cyst widely.

The surgeon's job is now for the time being over; succe now depends on not touching the parts until the cyst has extruded from the lung. This is achieved by the anæsthet who steadily increases the pressure in the anæsthetic circu so that little by little, over 10–30 minutes, the adventi cracks to the full length of the incision and the hydat gradually falls out of the lung intact and lies in the mackint bag. During this period there must be no attempt to h matters, and if the surgeon cannot be persuaded to lea well alone the safest instrument for him to use is a ster household spoon of appropriate size.

Once the cyst has herniated out of the lung it lies in the by the side of the lobe which originally contained it. operation table should now be tilted towards the surgeon that by tightening the lower margin of the bag the cyst lifted towards the surface and rolls naturally into a porri held to receive it. The moment when a hydatid rolls o of the lung intact is one of the most satisfying in surgery.

When the hydatid has been removed the surgeon m consider the best plan to adopt in relation to the "sac left in the lung. This has been dealt with in the pa already mentioned.

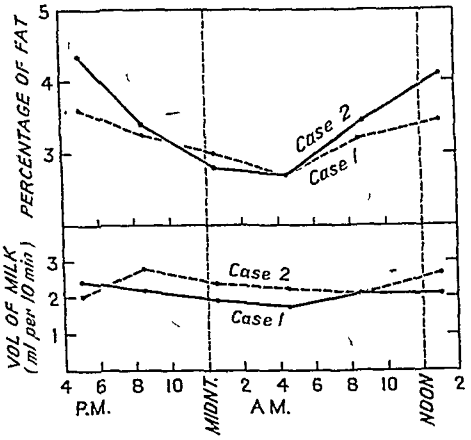
DIURNAL VARIATION IN THE FAT CONTENT OF BREAST-MILK

AVIS GUNTHER *   JEAN E. STANIER †
M.A., M.D. Camb.   M.A. Oxfd
Members of Medical Research Council Unit, Wuppertal, Germany

DIURNAL variation in the percentage of fat in cow's has been recognised for more than a century, a similar variation in human milk has also been ribed by Plauchu and Rendu (1911), Denis and ot (1919), Deem (1931), and Nims et al. (1932). e, in milking a mammary gland, the percentage of in the milk expressed rises continuously from first st, the percentage of fat in the whole sample depends part on the extent to which the gland has been ptied. In the ordinary process of milking a cow e total volume obtained is affected by the "letting wn" process, which appears to be a driving forward the alveolar contents brought about by the action posterior pituitary hormone on contractile elements the gland. Variations in the percentage of fat in the hole sample due to less or more hind milk being cluded in it can be greater than the usual range of urnal variation.



1—Percentage of fat and volume of milk obtained 4-hourly roughout 24 hours with injections of pitocin 1 unit (cases 1 and 2).

The secretion of fat in cow's milk has recently been udied by a more exacting technique. An intravenous jection of 'Pitocin' has been given at the end of e ordinary milking and the extra fluid available pressed. By milking in this way at constant intervals roughout the day and night an almost constant rcentage of fat has been obtained in all milkings ter the first (Shaw 1942). The doubt which this ork cast on the reality of diurnal variation in women as increased for two other reasons: (1) in all the reports variation in the percentage of fat in human milk e investigators had allowed a long night interval, hich in itself might have caused the percentage of t to vary; and (2) where the observations were rried on for three days the variation had almost isappeared by the third day (Nims et al. 1932).

The present investigation was made to determine hether the percentage of fat in human milk showed a iurnal variation despite complete and regular emptying the breast—i.e., whether the variation depended on hanges in the formation of the milk—and whether if ere was such a variation, the percentage of fat could be made more constant by feeding the mother by night as well as by day.

DIURNAL VARIATION IN WOMEN RECEIVING NO FOOD SUPPLEMENTS

The variation in percentage of fat during 24 hours was studied with the aid of pitocin injections in two women (cases 1 and 2) on the tenth and eleventh days after delivery. The milk samples were always withdrawn from the same breast at intervals of 4 hours by day and night by the same investigators. The baby took the other breast 4-hourly, five times during the 24 hours, immediately after the emptying of the breast used for sampling. The babies were not fed at midnight. The same technique was used at each milking-time: after the breast had been milked as dry as possible by manual expression, one unit of pitocin was injected intravenously and the breast was milked again by further manual expression. In these two women the dose of pitocin caused a few drops of milk to run from both breasts each time, and a considerable volume of milk, as much as a quarter of that already milked out, was obtained.

The percentage of fat in the entire milk sample was estimated in duplicate by the Gerber method.

Fig. 1 shows the percentages of fat and volumes of milk obtained from the two women. Despite the almost constant degree of emptying, as shown by the approximately level line for volume, there was a definite and regular variation in the percentage of fat in the milk.

DIURNAL VARIATION IN RELATION TO FOOD INTAKE

The influence of food on these diurnal variations was studied in six women (cases 3–8) by sampling the milk 4-hourly for 52 hours and by giving the women, during one of the two nights, food of sufficient calorie value to make the intake about the same throughout the 24 hours. Three women received the supplementary food during the first night of the experiment and three during the second. The supplements consisted of sugar and milk in coffee, and cakes made of flour, sugar, and margarine. All the women were primiparæ except one who had borne two children. The investigation was begun between the eighth and the eleventh day after delivery.

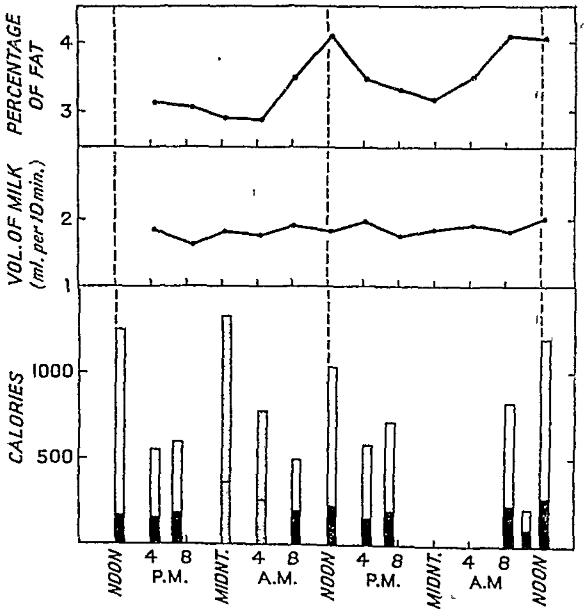


Fig. 2—Percentage of fat and volume of milk in case 3 given pitocin 2 units 4-hourly. Columns represent calories in meals, the darker bases showing the amount taken as fat; stippled columns represent additional food taken at night.

Now at the Obstetric Hospital, University College Hospital, London.

Now at the Department of Biochemistry, Oxford University.

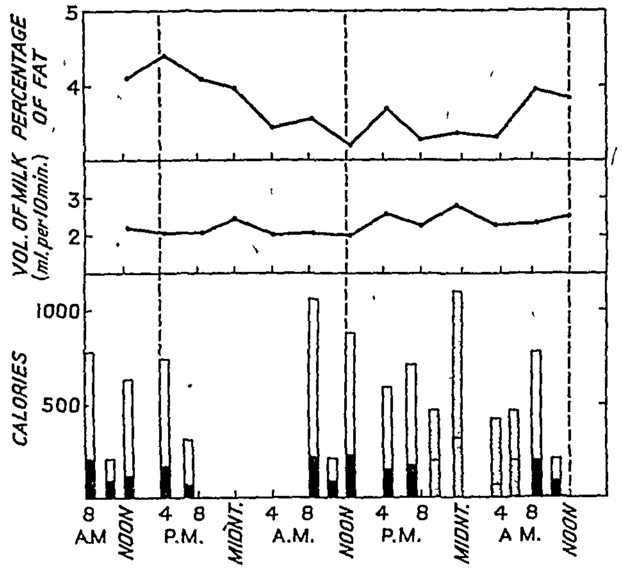

Fig. 3—Percentage of fat and volume of milk in case 4 given pitocin at initial emptying and at taking of first five samples only.

The technique of emptying described above but with doses of two units of pitocin 4-hourly was used throughout the investigation on case 3 (fig. 2). In cases 5–8 (figs. 4–7) the 4-hourly emptying was made without pitocin. In case 5 (fig. 4) pitocin injection was tried repeatedly at the outset; but, though it caused a few drops of milk to exude from the nipple, no extra milk could be expressed. Case 4 (fig. 3) received pitocin at the initial emptying and during the taking of the first five samples; but, since she felt faint after the injection at 4 A.M., the pitocin was discontinued.

Figs. 2–7 show the variation in the percentage of fat in the milk withdrawn 4-hourly from these women during the two days. Since the time taken to withdraw a sample was an appreciable part of the 4 hours of an interval, the recorded moment of sampling was the time when the withdrawal was completed. In some instances this moment was as much as 10 minutes before or after the intended one. To take into account this small variation the volume of milk obtained has been divided by the length of the interval. In figs. 1–7 the volume is given as the number of ml. of milk obtained per 10 minutes. The columns in figs. 2–7 indicate by their height the total calories taken, the darker portion at the base of each representing the calories taken fat. The stippled columns represent supplemen food. In cases 3 and 5 it can be seen that, in spit the constant volumes obtained at each milking, t was a pronounced diurnal variation. Only case 4 s no clear variation, and this may have been due omission of the pitocin injections after the fifth sa

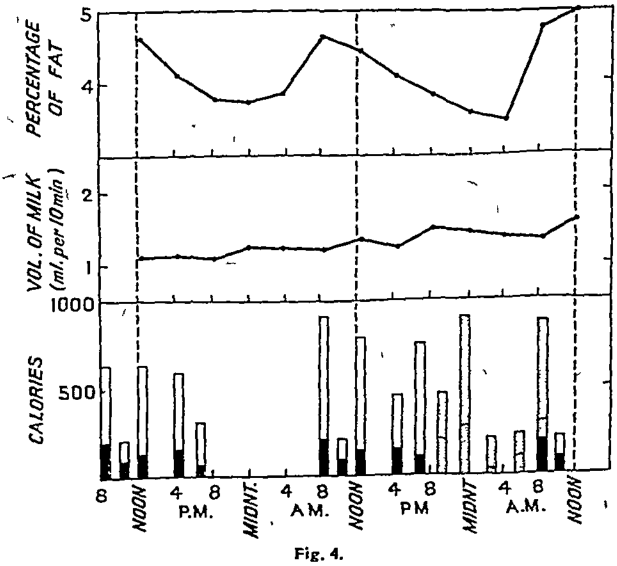

Fig. 4.

The six cases together demonstrate clearly that rise and fall in the percentage of fat in the milk did depend on the time of intake of food or on the am of fat it contained. There was a conspicuous rise in percentage of fat in the milk secreted between 4 and 8 A.M. even when the mother had taken no for 12 hours, except for breakfast eaten immedi before the 8 A.M. sample was withdrawn. Conve the percentage of fat fell during the day, when f was being taken. No evidence was obtained that f might have a delayed effect, for the changes were same whether the mother was given some or no f during the previous night. Activity on the part of mothers also seemed to have no effect; for, though 4–8 A.M. rise in the percentage of fat followed the

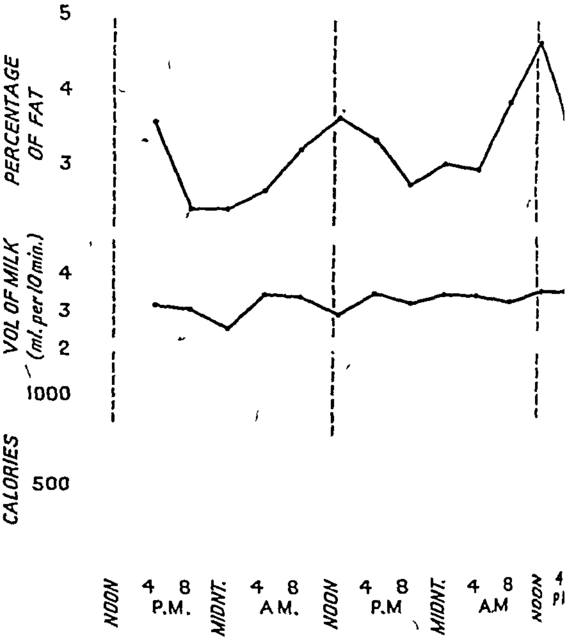

Fig. 5.

morning duties, the mothers merely fed their babies that time, washed themselves, and returned to be They were most active in the late afternoon, 12 ho later, and then the percentage of fat was falling.

DISCUSSION

The diurnal variation in the percentage of fat in milk from women who received pitocin is essenti similar to that reported by Deem (1931) and Nims et (1932) and resembles that of the women who, in present investigation, received no injections. The de of the variation was very little, if any, smaller w the removal of milk was aided by pitocin than whe was not. In the present investigation the richest was secreted in the morning, as it was in those of D and of Nims et al. The nadir seems to vary betw 8 P.M., midnight, and 4 A.M.

In Ružičić's (1936) 10-day study of five wom the percentage of fat in the milk varied according the diet. When the mothers lived on bread alone 3 days the variation in the percentage of fat was v small; when the mothers received a mixed diet percentage of fat was highest in the morning witl

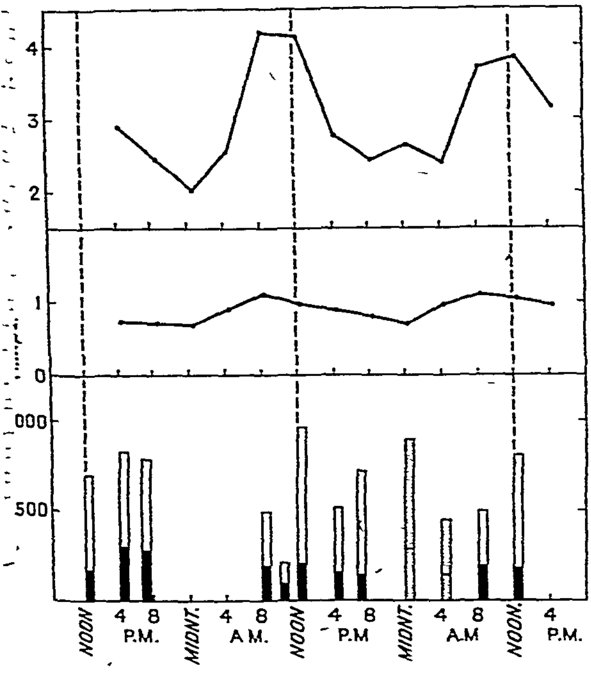

Fig. 6.

ond peak in the evening ; and, when for 3 days the thers ate only bread except for a daily dose of butter 9 g. (about $^1/_2$ lb.) taken all at one time, the richest lk was obtained about 12 hours after the ingestion of fat. Ružičić concluded that the time of day per se not affect the percentage of fat, but that the varians depended on the diet. Our findings do not agree h those of Ružičić.

The mechanism underlying the diurnal variation nains a subject of conjecture and is being further estigated.

If the variation is of benefit to the baby, the reason not immediately apparent. Possibly the poorer milk the early morning enables the baby to take more id and so to replace the night's loss of water. Curiously ough, the customary routine of breast-feeding is likely to add to the disparity in the percentage of fat due to diurnal variation. The long night interval and the 3-hourly or 4-hourly feeding during the day probably provide the baby with milk with a lower percentage of fat on waking, since the breasts are seldom emptied then, and even richer milk at midday by inclusion of the rich residual hind milk from the early morning. The small volume of milk often taken at 2 P.M. is perhaps a physiological response on the baby's part to the richness of the milk at that time.

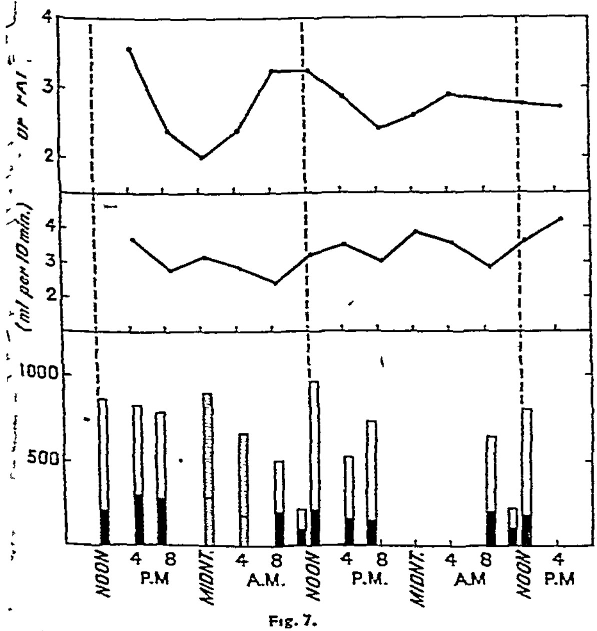

Fig. 7.

gs. 4-7.—Percentage of fat and volume of milk in cases 5-8, not given pitocin.

SUMMARY AND CONCLUSIONS

An investigation was made to discover whether the diurnal variation in the percentage of fat in breast-milk, reported by previous workers, was caused by changes in the secretion of milk within the breast or by varying proportions of hind milk being included in the samples.

A diurnal variation was found even though the breast was emptied at constant intervals and the emptying completed with the aid of intravenous injection of pitocin. This variation is therefore attributed to variations in the composition of the milk being secreted. It was not related to meal-times, and was unaffected by the administration of food during the night.

This investigation forms part of a study of the relation of diet to the composition of breast-milk which has been carried out in the Landesfrauenklinik at Wuppertal. Grateful acknowledgment is made to Prof. K. J. Anselmino, director of the clinic, for hospitality, and to Dr. A. von Finck for assistance. Our warm thanks also go to Prof. R. A. McCance and Dr. E. Widdowson for much help and encouragement.

Both investigators were in receipt of grants from the Medical Research Council.

SLOUGHS OF THE TRACHEAL MUCOSA

F. L. TURNER
M.B. Edin., D.A.
ANÆSTHETIST, LEICESTER THORACIC UNIT

MUCH has been written about the need for a gas-tight system when a closed-circuit method of anæsthesia is used. Very little has been mentioned about the dangers which may follow the use of the cuffed type of endotracheal tube. This type of tube is often advised to ensure that the circuit is leak-proof, and the cases described below give adequate warning of the dangers inherent in this technique.

Hewer (1946) has drawn attention to tracheitis as a complication of endotracheal anæsthesia, especially in operations on the thyroid gland: and it has been shown that the use of biniodide of mercury for the sterilisation of tracheal tubes has caused the tracheal mucosa to slough (Ransome 1947). Lundy (1944) believes that there are patients whose mucosæ cannot tolerate any trauma: but such patients must be rare.

Hewer (1946) has also indicated a reliable method for ensuring the proper inflation of these cuffs, and this was adopted in cases 1 and 2 described below.

Case 1.—A woman, aged 25, underwent a left lower lobectomy, with removal of the lingular process, for bronchiectasis on May 17, 1948. After operation her condition and progress were satisfactory, but she had a peculiar high-pitched wheezy cough, which seemed to be associated with a moderate degree of obstruction to the expulsive effort, as though the glottis were partially occluded. A slough was removed from the trachea by bronchoscopy on May 19. This gave complete relief from wheezing and obstruction, and the patient made an excellent recovery.

It was thought in this case that the slough might be a bronchial cast, but it was difficult to see how it had escaped removal at the bronchoscopy which was done at the end of the operation.

Case 2.—A woman, aged 27, underwent pneumonectomy *on June 10, 1948,* for total bronchiectasis of the left lung. Her postoperative course was satisfactory, except that she had the high-pitched wheezing type of cough, associated with partial expiratory obstruction, which had been noted in case 1. This cough made us suspect that a slough might be present in the trachea, and on June 13 a slough was seen and partially removed by bronchoscopy. Complete removal was impossible, because a small portion remained adherent to the tracheal mucosa about 1 in. proximal to the carina. There was considerable improvement in the patient's symptoms after this partial removal, but there remained some wheezing, and her coughing was not entirely free from embarrassment. At a second bronchoscopy, on June 17, the remaining portion of the slough was removed. At this time a roughened area of mucosa was seen on the whole circumference of the trachea, extending in a proximal direction for about 1 in. from the place at which the slough had been adherent at the previous bronchoscopy.

This evidence was taken as sufficient to dispel any idea of bronchial casts, and attention was directed to the anæsthetic technique.

In these two cases the endotracheal tubes were no. 9 'Portex' Magill tubes, and a rubber cuff had been slipped on to each one. Inflation was by the method recommended by Hewer. There is no evidence that the plastic tubes were in any way responsible for the damage, and at no time was biniodide of mercury used in the sterilisation of the tubes or cuffs.

The same technique had been used in a large series of thoracic cases, and we had not noted any such catastrophes up to the time of the first case here recorded. There can be no doubt that the sloughs were caused by pressure; in short, the cuffs were too tightly inflated.

There are certain differences in case 3 which make it important to review the technique used.

Case 3.—A boy, aged 11 years, had his left lower lobe removed for bronchiectasis on July 20, 1948. He was uncooperative and had to be urged to cough. On July 23 he had developed the characteristic cough, and bronchoscopy was done at once. A slough was found adherent to the vocal cords, and bits of this were removed. Again on July 24 pieces of the slough were removed, but a portion still adhered to the cords. His progress was satisfactory, apart from the intense trouble we had in making him cough. During the night of July 27 he suddenly became cyanosed and collapsed, and by the time assistance arrived his state was such that bronchoscopy was easily done without an analgesic. A fairly large piece of slough had become wedged between the cords, and its removal immediately relieved the cyanosis. His further convalescence was uneventful, and his final recovery complete.

A no. 6 rubber Magill cuffed tube was used on this child at operation; the cuff was not inflated. The position which we adopt for lobectomy is a slight modification of that described by Brown (1948), and the child's head was sharply turned to the right during the operation. There can be no doubt that the angle at which his head was turned forced the tube hard against the vocal cords and probably the larynx and perhaps the upper centimetre or so of the trachea, with the unfortunate results described.

An adult will probably cough up such a slough without much trouble when it becomes free to move in the trachea; if this were not so, we should probably have heard more of these sloughs since cuffed tubes must often be used in patients undergoing upper abdominal section. In children, however, the glottis is too small to allow the expulsion of a slough such as we have described, and the congestion rapidly produced by anoxia only makes matters worse, while anoxia will of itself abolish the efforts to cough and expel the foreign body.

It is doubtful if these sloughs would have bee had the patients not been treated in a thoracic for the adults would probably have expelled their sl and the child would almost certainly have died a bronchoscope could have been brought. N would have revealed the true state of affairs, bu unlikely that the cause would have been realised isolated case.

I wish to thank Mr. B. Winter, assistant surgeon Leicester Thoracic Unit, for his helpful criticism and timely interventions with the bronchoscope.

MEGALOBLASTIC ANÆMIA IN CŒLI DISEASE TREATED WITH FOLIC A

M. L. Thomson
M.A., M.D. Aberd., F.R.C.P.
PHYSICIAN

H. W. Dalt
M.B. Dubl
PREVIOUSLY PATHO

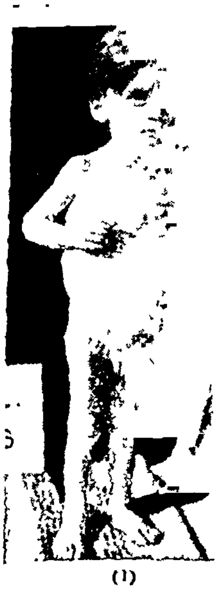
Vera K. Wilson
M.Sc. Manc.
BIOCHEMIST

ROYAL MANCHESTER CHILDREN'S HOSPITAL

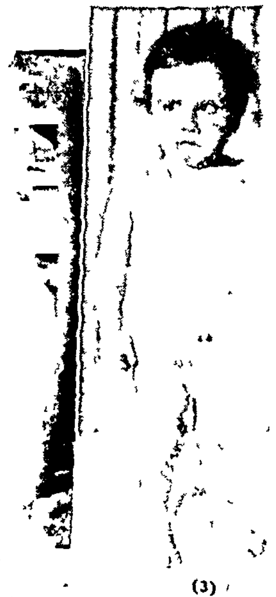
In 1946 we published a brief note on two ca megaloblastic anæmia in cœliac disease (Dalton 1946). These have now been fully investigated as re analysis of fat in the fæces, glucose-tolerance blood-counts, marrow biopsies, radiography of gastro-intestinal tract, Mantoux tests, examinati duodenal juice for trypsin and lipase, and exami of fæces to exclude parasites, &c.

Case 1.—A boy, aged 2 years 2 months, was admi hospital on April 23, 1946, with a history of losing and passing frequent pale bulky offensive stools. At th of 1 year he had had diarrhœa and vomiting. His abd had then been unduly large and his motions offensiv bulky, containing mucus but no blood. He had been t in another hospital for some months.

On admission he was a miserable wasted child with a distended abdomen (fig. 1). No other specific signs found.



(1)



(3)

Fig. 1.—Case 1 on admission.

Fig. 3.—Case 1 after three months' treatment with folic acid.

stigations.—The fæcal fat was estimated on five occa- n eight months. An excess of fat averaging 49·10% d fæces (maximum 56·14%, minimum 35·50%) was ; on the three occasions when the patient was on y diet. The excess of fat was in the free fatty acids occasion and in the combined fatty acids on another. the patient was on a high-protein low-fat diet, the at averaged 18·9% of dried fæces (maximum 20·37%. um 17·46%). Oral glucose-tolerance tests (Hagedorn nsen 1923) done on six occasions in eighteen months onsistently flat curves, the greatest rise in blood-sugar 29 mg. per 100 ml. Duodenal juice contained a normal ty of trypsin (Andersen and Early 1942). No parasites ound in the fæces. Radiography of the gastro-intestinal fter a barium meal showed clumping of the barium in um. A Mantoux test was negative. His red-cell count t. 9, 1946. was 4.500,000 per c.mm., Hb 79%. The lls varied in size and somewhat in shape, and stained . The mean cell diameter was about 8·0 µ (halometer d). Many macrocytes were present (10–12 µ by eye- nicrometer). Sternal marrow (Sept. 26. 1946) showed nucleated cells per c.mm.:

Cells	*Percentage*
Promyelocytes	10·0
Myelocytes	4·0
Metamyelocytes	5·5
Staff cells	7·5
Polymorphs	5·0
Eosinophils	0·5
Basophils	0·5
Lymphocytes	17·0
Normoblasts	34·5
Megaloblasts	11·0
Unclassified cells	0·5
Mitotic cells	0·5
Giant staff cells	0·5
Monocytes	3·0

atment and Progress.—Folic acid 5 mg. daily was begun t. 3, 1946, together with iron and ammonium citrate t.d.s. and ins A, D, C. Con- t clinical ovement ed (fig. 2). ct. 3, the weighed lb. He till miser- and silent, could be aded to only with difficulty. ongue was dsmooth, kin loose abby, and abdomen ded. On 21st he d stand pported talk, and as much cheerful. On the 28th he would call out and play in bed, and he now seemed happy. From Dec. 5 acid 5 mg. was given twice weekly instead of daily. an. 18, 1947, the child weighed 28 lb., was happy, ble to run about the ward. Apart from improved nutrition itality, the steatorrhœa, abdominal distension, and radio- l appearances remained materially unchanged, and the se-tolerance curve remained flat. On Dec. 9 the child very fit, but his abdomen was still distended (fig. 3), æces contained 35·5% of fat, and the oral glucose- nce curve was still flat. The patient was discharged n. 6, 1948, and in September, 1948, his mother wrote his condition was satisfactory.

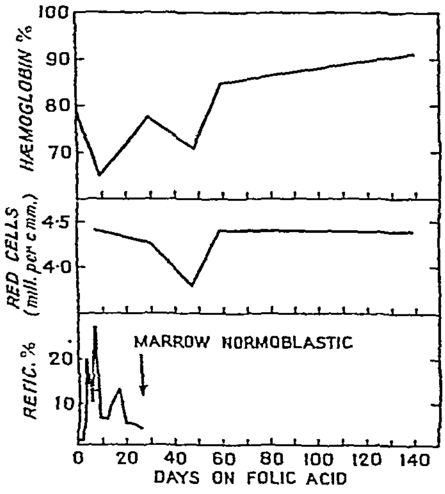


Fig. 2.—Blood response to folic acid (case 1).

se 2.—A boy, aged 1 year 6 months, was admitted to tal on June 25, 1946. He had been well until the age of onths, when he had had diarrhœa and vomiting for three hs. After this he had improved, but the diarrhœa had recurred. His stools had contained mucus but no blood, and his abdomen had enlarged.

On admission he was a miserable wasted child, with a distended abdomen and visible intestinal movements. The stools were yellow, loose, and offensive, but not bulky.

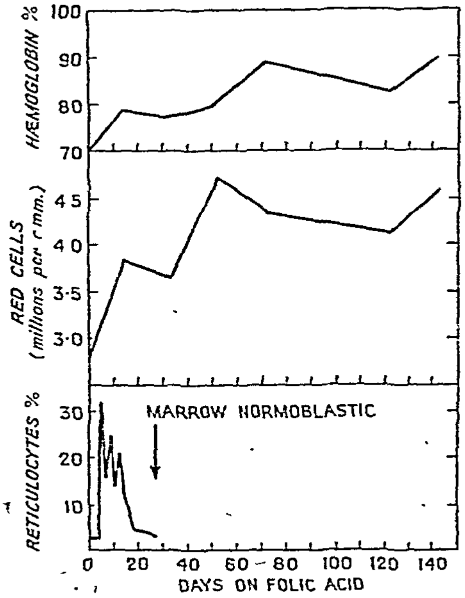

Fig. 4.—Blood response to folic acid (case 2).

Investigations.—The fæcal fat was estimated on five occasions in nine months. Each time an excess in total fat was present, averaging 41·95% of dried fæces (maximum 52·30%, minimum 31·59%), and the neutral fat was normal. The excess of fat was in the combined fatty acids on two occasions, and in the free fatty acids on three. Oral glucose-tolerance tests done on four occasions in five months gave consistently flat curves. Duodenal juice showed a normal quantity of trypsin; lipase was present. No parasites were found in the fæces. Radiography of the gastro-intestinal tract after a barium meal showed clumping of barium in the ileum. A Mantoux test was negative. A fractional test-meal showed complete achlorhydria. The red-cell count on Aug. 9, 1946, was 3,370,000 per c.mm., Hb 83% (Haldane). Anisocytosis was fairly well marked, and a good many macrocytes were present. Most of the cells stained well; a few polychromasic forms were seen. Sternal marrow (Sept. 26, 1946) contained 47,900 nucleated cells per c.mm.:

Cells	*Percentage*
Promyelocytes	2·0
Myelocytes	9·5
Metamyelocytes	13·0
Staff cells	5·5
Polymorphs	4·5
Eosinophils	6·0
Basophils	0·5
Lymphocytes	19·5
Normoblasts	16·0
Megaloblasts	20·0
Unclassified cells	2·5
Mitotic cells	1·0

Treatment and Progress.—Folic acid 5 mg. daily was *given* starting on Oct. 3, 1946, together with iron and ammonium citrate gr. 10 t.d.s. and vitamins A, D, and C. The response is shown in fig. 4. At the start of this treatment he weighed 17 lb. 7 oz., was very miserable, and could not stand without support., His tongue was smooth and red, his gums spongy, and his abdomen not much distended.. There was general wasting, severe pallor and a very poor appetite. On Oct. 25 the child weighed 19 lb. 6 oz. On the 29th he could stand unsupported, but still showed little activity though temperamentally more cheerful. On Nov. 16 he weighed 20 lb. 4 oz. On Nov. 19 there was some deterioration in his general condition but his weight was maintained. On Nov. 22 he developed measles. On Dec. 21 he weighed 21 lb. 3 oz. and was eating well; his general condition had improved. On Jan. 10, 1947, he was discharged from hospital on a maintenance dose of folic acid 5 mg. twice weekly.

On June 22, 1947, the boy was readmitted to hospital. Improvement had been maintained until two weeks before, when he had begun to pass watery stools. He was irritable, unhappy, and moderately dehydrated, with a slightly distended abdomen. He was put on a cœliac diet, vitamins A and D, 'Hepargiandol B' 1 ml. twice weekly, and folic acid 5 mg. weekly. The diarrhœa improved. His red-cell count on July 1 was 4,250,000 per c.mm., Hb 82%. On July 9 fæcal fat was estimated as 39·06% of dried fæces. On July 16 the patient weighed 23 lb. 8 oz., and on Aug. 6 20 lb. 2 oz. On Aug. 9 he was sent home.

On Sept. 12, 1947, the child was again admitted to hospital, having developed generalised œdema two weeks earlier. He was now emaciated, with œdema of the face, limbs, and sacrum, and he weighed 19 lb. 10 oz. His total serum-protein level was 3·30, serum-albumin 1·86, and serum-globulin 1·44 g. per 100 ml.; albumin/globulin ratio 1·29. Blood-urea 45 mg. per 100 ml. The child was given double-strength plasma, followed by 'Casydrol' intravenously and high-protein 'Trufood' by mouth. On Sept. 20 his œdema was less, and on the 23rd the intravenous amino-acids and dextrose were repeated, considerable improvement following the infusion. On Sept. 27 the child developed tetany, which responded to calcium gluconate given intramuscularly. Further treatment with intravenous amino-acids, folic acid, &c., produced no response, and his general condition deteriorated rapidly. The œdema increased and death followed the onset of bilateral otitis media and bronchopneumonia.

Necropsy Findings (Dec. 12, 1947).—Bronchopneumonia, otitis media, and duodenal ulcer were found. The body, examined 10 hours after death, was emaciated, with slight œdema of the ankles, and practically no superficial fat. The middle ears contained thick yellow pus. Gram films showed numerous pus cells and pneumococci; cultures grew moderate numbers of *Staph. pyogenes* and coliform organisms. Both lungs showed œdema and inflammatory consolidation. The right ureter was dilated, but the left healthy. The duodenum had an ulcer measuring 7 x 4 mm. about 1 cm. from the pylorus, its long axis being at right angles to that of the intestine. Many segments of the small intestine were dilated and atonic; these were separated by short more or less normal segments.

Histology.—The lung showed the usual appearances of bronchopneumonia. In the pituitary gland there was a complete absence of acidophil cells. The liver and small intestine appeared to be normal.

COMMENTS

These cases showed the classical signs of cœliac disease. Our hopes that folic acid would prove a cure have not been fulfilled. We cannot say that folic acid achieves any better blood response than might have been obtained with liver.

The incidence of megaloblastic anæmia in cœliac disease is small. We have examined the marrow in 11 cases without finding such another. However, a further case has been reported to us by Dr. M. Egan, and the presence of megaloblastic anæmia was verified by Dr. M. C. G. Israëls. We understand that investigations at the Hospital for Sick Children, Great Ormond Street (I. A. B. Cathie, personal communication), Edinburgh (Innes 1948), Liverpool (Hay 1948), and Sheffield (J. L. Emery, personal communication) have not disclosed any further cases.

SUMMARY

Two cases of megaloblastic anæmia in cœliac disease are described.

After treatment with folic acid both children improved.

In one case the improvement has continued, but in the other it was only temporary and the child subsequently died; the necropsy findings are given.

We are indebted to the late Dr. C. P. Lapage for permission to treat case 2 with folic acid, and to Dr. T. N. Fisher for allowing us to make observations on case 1.

VOLVULUS OF THE CÆCUM PRESEN AS A STRANGULATED INGUINAL HE

H. D. Moore
M.C., M.B. Sydney, F.R.C.S., F.R.C.S.E.
SURGICAL REGISTRAR, RADCLIFFE INFIRMARY, OXFC

THE hernial sac is the foremost thought of any s in the examination of the acute abdomen, and w hernia is found it usually explains the symptoms. at times enlargement of the sac is associated though not the cause of, the symptoms—it m filled with pus and an acutely inflamed appendix o food and fluid from a perforated ulcer, or it may c clear fluid from a tuberculous peritonitis, causing t in diagnosis during an exacerbation.

The following case underlines the importance of th beyond the hernia, even when it is irreducible, a thoroughly examining the intra-abdominal portion gut involved, for the hernial sac, containing strang bowel, masked a more serious condition.

A man, aged 76, was admitted to the Bristol Infirmary on the evening of March 23, 1948, with c *abdominal pain and an irreducible hernia which* had painful for six hours. He had vomited several time only stomach contents, and had passed no flatus or since his pain began. The hernia, which had been p for many years, had previously given no trouble and ha readily reducible; there was no history of previous a of abdominal pain, nor of effort, overeating, or dia before the onset of this illness.

The patient did not look ill and did not seem to much pain. His tongue was slightly furred but temperature 98·4°F, pulse-rate 90, and respirations min. There was a rounded, tense, and tender swelli the groin about 3 in. in diameter, which was diagnose strangulated inguinal hernia, with slight general, b localised, distension of the abdomen, and bowel sound heard in all areas. Rectal examination showed on empty rectum. Otherwise no greater abnormality was than would be expected with his years, which he carrie A Ryle's tube was passed into the stomach, but only fluid was drawn off.

Operation was begun, about an hour after adm under local anæsthesia, 75 ml. of 1% procaine being but was continued under general anæsthesia with cyclopr and oxygen, because the patient resented the handli his bowel. The incision was made parallel to the in ligament, and the hernial sac was exposed and opened usual way. It contained cæcum on the right, small and a Meckel's diverticulum on the left, all a mauve c and some bloodstained fluid. The hernia was direct, an opening into the peritoneum large and not constricti bowel. A finger inserted into the peritoneal cavity came on the mesentery of the bowel, which was twisted o

The incision was enlarged laterally by cutting the and the strangulated bowel was delivered. It consis ascending colon and cæcum, on a long mesentery, and 3 ft. of terminal ileum, twisted anticlockwise through The ileum was untwisted, the bowel (which regained its colour) returned to the abdomen, and the wound repai

The patient's condition by this time was not good he had vomited, despite the previous gastric suction. a pint of plasma, given intravenously, there was consid improvement, but next morning he was obviously ill bubbling rhonchi all over his chest. He died 18 hours operation.

Necropsy Findings.—The peritoneal cavity con 100 ml. of foul-smelling brownish fluid; the last $2^1/_2$ small intestine was much congested, with a thin la fibrin on its peritoneal surface; and there was a M diverticulum 2 in. long 2 ft. from the cæcum. The c was congested and grossly œdematous, and the rest large gut was much dilated and congested and cont bloodstained fluid. Both lungs showed gross congestio the right lung early bronchopneumonia in the lower lob

DISCUSSION

Cæcal volvulus without a hernia has often described, but I have been able to find only five publ cases of volvulus of the cæcum associated with h atellani[1] described an example in a woman with a left oral hernia to her knee and symptoms of acute obstruction. sac contained cæcum, ascending colon, and ileum, but wed no obstruction at the neck. Cæcal volvulus was nd post mortem.

ohn's[2] case was in a woman of 65 with a similar condition a very large umbilical hernia. Again there was no obstruc- n at the neck of the sac and the torsion was intra-abdominal, ng a clockwise half-turn (180°). Cohn adds that Billroth l a case with a right inguinal hernia and the bowel twisted ough 360°, and Kaiser one with a right scrotal hernia and bowel rotated through 180°.

Jacobsen[3] reported a case in a man with a very large ht inguinal hernia, who had had recurrent attacks of ere pain for a year before his final illness. The bowel luced itself when the sac was opened at operation, and the vulus was only found post mortem. There was a complete ist (360°) anticlockwise.

These cases illustrate, with the confusing addition of hernia, the types of volvulus usually described:) acute, with symptoms of acute strangulation of the wel; (2) subacute, with a history of some hours or ys, in which the symptoms are moderate only, and in ich distension, which may be localised to the right le together with a visible and palpable swelling, is mmon; and (3) recurrent or chronic, characterised y pain and tenderness in the right side and a varying gree of distension, which is sometimes relieved by the ssage of much flatus.

The present case, apart from its association with a hernia, unusual in that the man was 76 (the usual age being 5–45), in the paucity of symptoms and signs, and in e lack of any predisposing cause such as overeating, xcessive effort, &c.

It is of interest that, as in the previously reported cases, ere was no obstruction at the neck of the hernial sac.

I wish to thank Mr. R. V. Cooke, F.R.C.S., for permission publish this case.

FATAL CORONARY OCCLUSION IN A GIRL AGED 16

W. G. MacDougall
M.B. Edin., M.R.C.P.E.
RAINEE MEDICAL SPECIALIST, EDINBURGH ROYAL INFIRMARY

SINCE coronary occlusion in children is exceedingly are, the following example is of interest.

In February, 1948, a female shop assistant, aged 16, was dmitted to Edinburgh Royal Infirmary under the care of Dr. W. D. D. Small. She had been well until fourteen days reviously, when on hurrying home from work she suddenly eveloped shortness of breath associated with a gripping pain xtending widely across the front of the lower chest and upper bdomen. She was compelled to proceed more slowly, and n resting at home both pain and breathlessness were relieved. Thereafter these symptoms recurred daily whenever she urried, and relief was always obtained with rest. On the enth day after the onset she consulted her doctor but did not ccept his advice to rest at home in bed. That evening she was rather more breathless than usual but obtained complete elief when she went to bed. In the early hours of the following norning she woke up with gross dyspnœa and severe pain n the middle of the sternum. These symptoms continued luring the following thirty-six hours, during which she also ad bouts of vomiting. She was then admitted to the ward.

Previous History.—In September, 1947, she had had an attack of pain in the right iliac fossa associated with vomiting and albuminuria. There was no history of rheumatism, chorea, diphtheria, or scarlet fever.

On examination she was a bright well-nourished girl of average body build, dyspnœic, and cyanosed. The apex-beat was in the sixth intercostal space in the anterior axillary line, heart-rate 130 per min., rhythm regular, and pulsation forcible. A gallop rhythm was audible in all areas, being best heard in the fourth left intercostal space close to the midline. The blood-pressure was 78/54 mm. Hg. Medium crepitations were heard at both lung bases. The liver was not enlarged. Specific gravity of the urine was 1·030, and a trace of albumin was present. Peripheral vessels and ocular fundi were normal. Electrocardiography was not done. Radiography showed much cardiac enlargement and congestive changes at both lung bases, with possibly a small effusion at the right base. There was no peripheral œdema.

Course.—The patient's condition rapidly deteriorated, and she died twenty-four hours after admission.

Necropsy Findings.—The heart weighed 400 g. All its chambers were much dilated, and there was evidence of previous hypertrophy in that the trabecular muscles were thickened, especially on the left side. The heart muscle was pale, soft, and very thin. A large infarct ten to fourteen days old involved the lower part of the interventricular septum, the anterior part of the apices of the left and right ventricles, and the posterior part of the left ventricle. In the upper part of the posterior wall of the left ventricle, towards the base, an extensive area of fibrosis indicated a previous myocardial infarction. At the apices of both ventricles small ante-mortem thrombi were attached to the ventricular wall. The mitral valve admitted three fingers, and no abnormality was present in valve cusps or chordæ tendineæ. In the area of infarction one of the posterior branches of the left coronary artery contained a thrombus. The descending branch of the left coronary artery was carefully dissected, but no area of occlusion, either partial or complete, was found. The lungs were bulky, firm, and very œdematous. There were many small subpleural hæmorrhages in both lungs and one larger hæmorrhagic area in the left lung. In the lung tissue under this large hæmorrhage was a moderate-sized infarct probably two or three days old. On tracing the pulmonary artery to this part of the lung a small ante-mortem thrombus was found. The liver showed chronic venous congestion and many small yellowish areas resembling focal necrosis. No anatomical or pathological abnormalities were found in other organs.

Microscopy of many sections of heart muscle showed areas of infarction of different ages—some less than two hours old, others seven to ten days and one small area of organised infarct more than three months old. Various vessels contained thrombi, and a small section of one of these vessels supplying the area of recent infarction showed a localised acidophil necrotic appearance, with polymorph infiltration. In one of the lung sections recent thrombi were seen in the pulmonary vessels, but the vessel wall showed no sign of necrotic or degenerative change. In the kidneys, intestines, lymph-nodes, liver, spleen, and bone-marrow there was no evidence of primary arterial disease.

DISCUSSION

Evans and Graybiel (1948) discuss a fatal case of coronary occlusion in a girl, aged 18 years 11 months, in which there was hypertensive heart disease and gross arteriosclerosis. Shivelhood (1948) describes infarction in a boy, aged 12 years, who was diabetic from the age of 2 years. The youngest patient in Cassidy's (1946) series of 1000 cases of coronary disease was aged 26, and of Newman's (1946) 50 Service patients with coronary thrombosis the youngest was aged 20.

In the present case the earlier infarct situated towards the base of the heart appears to have developed without the production of classical symptoms; nor did its presence have any adverse effect on physical activity before the onset of the terminal illness. The small area of arterial necrosis, which was considered too pronounced to be purely a response to the thrombosis, was probably a true arteritis and responsible for initiating the thrombosis. In Newman's cases 37 of 39 showed the usual degenerative changes, and in 29 of these there was no thrombosis. Leary (1941), on the other hand, believed that the pathological lesion in the younger group was a subendothelial fibrosis, with necrosis of the intima leading to thrombosis. The present case confirms this view.

I wish to thank Dr. W. D. D. Small for permission to publish, and Dr. A. Cunningham for the pathological report.

For TOPICAL application

in allergic dermatoses

'Benadryl,' the potent antihistamine agent and antispasmodic, is now available for topical application as a cream containing 2 per cent of the drug in a specially prepared water-miscible base.

'Benadryl' Cream may be used either alone or to supplement oral or parenteral therapy. In the treatment of atopic or contact dermatitis and erythema multiforme it has additional value as an antipruritic, reducing the erythema, œdema and pruritus met with in these conditions.

'Benadryl' Cream

'Benadryl' Cream has also been found to be of benefit in the treatment of some cases of pruritus ani, pruritus vulvæ, neuro-dermatitis, bee-stings and insect bites.

Available in 1-oz. collapsible tubes and 1-lb. jars

Splenectomy and the Hæmatologist

INTEREST in splenectomy does not diminish. The chnique of the operation is well enough settled : the bjects for discussion are which patients will benefit om splenectomy, how can they best be chosen, and what cases should removal of an enlarged spleen be fused. In some conditions there is no argument—us for congenital hæmolytic icterus in the young atient splenectomy is the only sensible treatment nd success can be promised with confidence ; and n the other hand no-one nowadays would consider moving a spleen, however large, in chronic myeloid ukæmia. Between these extremes is a debatable eld that is getting larger. BODLEY SCOTT[1] has tely discussed the question from the physician's oint of view. For the surgeons, two series of cases ublished in America well illustrate this expanding eld. LAHEY and NORCROSS,[2] from Boston, Mass., st 83 splenectomies with only 2 deaths—a remarkable chievement, and even these 2, both patients with anti's disease, would not, they think, now be selected or splenectomy. Of their patients, 20 had congenital æmolytic icterus, 4 had splenic cysts, and 4 are lassed as “miscellaneous.” In 25 patients splenecomy was done for congestive splenomegaly and the esults are classed as “good” in no less than 17 of hem : idiopathic thrombocytopenic purpura was the ndication for 17, with 13 good results. Splenectomy as tried in 6 patients with acquired hæmolytic næmia, but in only one was the result satisfactory : was also tried in 7 patients with “panhæmoytopenia” and 5 responded reasonably well. The econd series is reported by COLE and others[3] from hicago. They list 87 cases with 7 operative deaths. of them in cases of Banti's disease, 1 in a patient ith acquired hæmolytic anæmia, and 1 classed as atypical aplastic anæmia.” They also have a large umber of cases of hæmolytic icterus and of thromboytopenic purpura, mostly with good results. In anti's disease, splenectomy was done for 13 cases, ut they have only 2 “good” results. The operation as done in 5 patients with Felty's syndrome (splenoegaly, panhæmocytopenia, and arthritis) ; in 4 he blood picture improved but the arthritis was naffected, while the fifth patient died a year later ith a malignant thymic tumour. They tried plenectomy for other odd cases with somewhat poor esults.

This willingness of surgeons to tackle cases that ot very long ago were thought unsuitable for splenecomy is based on changing views about the function f the spleen. The theory of “hypersplenism” has been much discussed in America, especially by DOAN, DAMESHEK, and their co-workers. This theory suggests that overactivity of the spleen may have a direct effect by an excessive destruction of blood-cells—erythrocytes, granulocytes, or platelets—in the blood passing through the organ ; or it may act remotely by inhibiting the output of these blood-cells from the bone-marrow or by inhibiting their maturation. In either case, hyperplasia of the bone-narrow will result, and, if maturation is disturbed, an undue proportion of early types of cells may be expected. It is here that the hæmatologist plays a part because interpretation and accurate assessment of the bone-marrow picture is needed. Difficulty arises particularly in the purpuras and in so-called splenic neutropenia and splenic panhæmocytopenia. These conditions may be both primary and secondary. Before splenectomy is recommended for them the primary nature of the case should be established, and the bone-marrow must be shown to be hyperplastic. Maturation changes are more debatable—for instance, as we noted in these columns last week (p. 202), most cases of thrombocytopenic purpura show only such changes as might be expected to accompany the hyperplasia. The secondary conditions include Hodgkin's disease, lymphoblastoma, tuberculosis, or Gaucher's disease, or the effects of drugs. LAHEY and NORCROSS have tried splenectomy for some of these, on the view that removal of the overactive spleen will relieve the anæmia and possibly the thrombocytopenia, and have noted at least temporary benefit. The disease variously known as “agnogenic myeloid metaplasia” or myelosclerosis must be excluded—often a difficult job—since in this the spleen takes over blood formation to compensate in part for a failing bone-narrow ; splenectomy, as COLE and others found, is soon fatal. In congestive splenomegaly, opinion for and against splenectomy has varied widely. LAHEY's[4] most recent opinion is that “we may have been too hasty in the past in condemning splenectomy entirely . . . in the early stages we believe that splenectomy still has a real value, unless one feels that an immediate shunt should be done.” COLE and others say that “careful evaluation of the patient . . . is essential and the decision for or against splenectomy is often difficult to make,” but they recommend the operation for any patient fit to stand the strain. BLAKEMORE,[5] however, would restrict splenectomy to cases with obstruction in the splenic vein ; all others should have a porto-caval anastomosis of some kind. These anastomosis operations are not easy, as speakers at the Royal Society of Medicine in January made clear,[6] but more surgeons in this country are learning and applying the technique. Finally, LAHEY and NORCROSS would extend the indications for splenectomy to include any patient who is known to have has an enlarged spleen for six months, has been exhaustively studied by a competent hæmatologist without the cause of the splenomegaly being found, and has no definite contra-indications. Study of these spleens, they rightly say, would do much to increase our knowledge of splenic pathology ; though that, by itself, would of course not justify a major operation in an otherwise fit person.

How do surgeons find their way through this jungle of difficult diagnosis and still have results like those quoted? The answer is that, if they are wise, they do not try. Lahey is frank about it. "The mortality of splenic diseases for which splenectomy is done," he says,[4] "will be controlled much more largely by the hæmatologist than by the surgeon." Mortality will depend on how well cases are selected by the hæmatologist, who must take the responsibility for determining whether the lesion is primary, or secondary to some condition for which operation would not be helpful. Cole and his colleagues say much the same. The hæmatologist, on whom these surgeons rely, is not a clinical pathologist: he is a physician, a clinician who is capable of making his own assessment and if necessary a personal interpretation of the hæmatological data and material—blood and marrow preparations and so on—in the light of the clinical picture as a whole. In this country hæmatology is often a subdivision of clinical pathology, and, as Piney[7] lately pointed out, we have too few hæmatological physicians and far too few beds are allotted to this specialty. Nevertheless the surgeon can obtain the necessary advice, if he knows where to look for it, possibly in his nearest teaching centre; and the number of splenectomies done in the dark, without benefit of hæmatologist, should steadily diminish.

Hearing-aids

The undertaking to supply a well-made, serviceable hearing-aid to every man, woman, or child in the country who needs it illustrates the new effort to ensure that the benefits of medicine are accessible to all. If there are objections to the instrument offered —the 'Medresco' hearing-aid—they cannot be stated too soon. On the other hand, they will never come too late; for the medresco is not an immutable structure and it is in process of development: mark II, now being manufactured, already shows improvements on the original design. Meanwhile it is interesting to know that both the research unit at Harvard University and the Medical Research Council's committee on electro-acoustics conclude that it is possible to produce a standard aid which will suit the very large majority of deaf people as well as any commercial aids on the market.

Steps have already been taken to meet some of the complaints about the medresco aid which have lately been published in a leaflet addressed to Members of Parliament by the British Association for the Hard of Hearing (B.A.H.H.). The leaflet asks why the aids were fitted with the "plug-in" type of earpiece, from which the rubber nipple is apt to detach itself and remain stuck in the meatus; but arrangements have now been made to overcome this difficulty by fitting individual inserts. It seems that many of the aids sent out until recently had loose switches, and made a grating noise when the volume control was used; but we are told that these defects, too, have been overcome in the mark II instruments. The B.A.H.H. further suggest that a test at the factory by an experienced user of aids would have saved many people from having to return their instruments—sometimes two or three times—for correction. Some clinics are now undertaking minor repairs and saving users this awkward necessity. But in case a test by a user of aids would not safeguar deaf from flaws in the instrument. Such tests sl be objective not subjective, depending on mea ment not opinion. A scientific test is of c carried out before the instrument leaves factory.

Users have from the start complained of the w of the batteries, packed in their solid leather case. case must be costly, and is felt to be unneces for, if the wire between the batteries were lo men could distribute them in their pockets, women in a suitable waist-belt.) Large bat were chosen, as was explained at the outset, so users need only renew them at long intervals; this advantage may well be offset by the w The B.A.H.H. also claim that medresco aids are issued to patients with nerve deafness who harmed by the use of an electrical hearing-aid. latter point is more controversial, and the evi does not seem to be clear. Children with deafness are not made worse by an electrical on the contrary, their hearing improves because aid enables them to learn *how* to hear. Adults no exact measure of hearing in their heads: they put on an aid they are astonished to find it is like to hear properly: they have forgotten sensation. When they remove the aid they equally astonished to find how badly they hear. is hard to make a critical judgment in such cir stances and they are apt to believe that their hea is worse than it was before they used the aid. thus natural to blame the aid for a supposed deter tion of hearing. On the other hand, a damaged n may conceivably tire more readily than a no one, and the hearing-aid might thus be floggi tired horse, even to the point of injury. The ques could be answered by appropriate investigation, until there is objective evidence of damage it sh not be pressed as an objection to the aid.

More serious, perhaps, is the allegation that aids are relatively scarce. Up to this July 27 had been issued by the Ministry,[1] but the B.A. estimate that some 150,000 are needed. At pre the clinics are crowded, and waiting-lists have mounting steadily. We have heard of one where it has been necessary to close the waiting for the time being, and there is no prospect reopening it for nine months. This situation m however, be seen in perspective. It is a wast time and money to give people aids without at same time giving them proper training in their The present crisis is transient: in time ever will be fitted, and the pressure on the clinics subside. There are not enough trained people t aids faster than is being done at present; bu would hardly be worth training large number meet the present strain on the clinics, since t services would soon become redundant. The who have waited so long for this piece of service, be patient a year or so if the situation is expla to them.

The B.A.H.H. express a fear that the produc of hearing-aids may become a Government monop

1. See *Lancet*, July 16, p. 137.

t it has already been responsibly stated that the vernment do not intend to take over the industry. d this will go some way to safeguard existing users commercial hearing-aids. who will still be able to adjustments and repairs done by the makers. It ms that. before the National Health Service was mched. any person who was hard of hearing could adily get an appointment at a hospital clinic where would be examined by a consultant: if his case emed likely to benefit by an aid he would then try rious kinds. decide which he preferred. and be ven a note from the hospital to have one like it a week's trial. If he bought it, he was given 25% scount. The association hoped this service would continued alongside the issue of the medresco aid. it there are obvious objections to such an arrangement. The medresco is a sound workmanlike job. out the most powerful instrument for its size at esent manufactured; but it is designed to suit the r. not to attract the eye. Commercial aids often ok neater. and some of the 90% or so of patients ho would be suited by a medresco might think nother model preferable on grounds of appearance ly. The deaf have sometimes been treated very fairly in the past. and an important aim of the edresco aid is to protect users against exploitation. or would it be justifiable just now to use the limited ained staff in the clinics to fit commercial aids. s we have said already. careful training of the user s essential with any kind of aid, and it is important hat it should be begun in the right atmosphere: for hough it is simple to measure the effect of an aid n the patient's hearing. it may be difficult to make im realise its full value. Hearing. like other sensations. can only be appreciated subjectively. and motional factors inevitably influence a patient's pinion of his hearing-aid: none so deaf as he who hinks his aid a failure in advance.

Experiments on Animals

MOST people in Great Britain regard laboratory xperiments on animals as an unpleasant necessity. hey accept the practice because so much good has ome of it: but they have ensured by legislation that shall be used as sparingly as possible, kept in the ands of those believed to be humane and responsible. nd safeguarded by legal restrictions from abuse. his position has not been reached by following any principle to its logical conclusion. Indeed, principles arried to that extreme. and then used as rules of onduct, often prove cruel or silly or both. Clearly t is as wrong to let a child die unnecessarily of diphheria as it is to regard all animals as a lower creation lesigned to suffer for the benefit of man. Though oth attitudes can be justified on principle. both offend our humanity. We are thus compelled to reat this like other moral dilemmas. and pick our way uneasily along a middle course. never wholly at peace with our consciences. but at least sparing them the final outrage of one gross evil or the other.

Certainly the compromise owes nothing to callousness. As long ago as 1871 the British Association for the Advancement of Science resolved that no experiment which can be done under an anæsthetic should be done without it: that no painful experiment is justifiable for the mere purpose of illustrating a law or fact already demonstrated (i.e.. such experiments should not be used in teaching); and that when, to obtain a new fact. it is necessary to undertake a painful experiment. every effort should be made to ensure success. so that pain is not inflicted uselessly. The Cruelty to Animals Act of 1876 was founded on this outline: it obliges those who wish to conduct painful experiments. or " any procedure calculated to interfere with the normal health and comfort of an animal," to obtain a licence from the Home Secretary; and it further requires that an animal suffering from severe pain which is likely to endure should forthwith be painlessly killed. whether the main object of the experiment has been attained or not. Moreover, there is now a well-grown opinion among scientists that animals should not be used in large numbers for painful experiments if the facts can be established equally well by the use of a few. Within this frame of regulations and customs it is possible to limit painful experiments to a very small proportion of experiments as a whole. and to ensure that the suffering experienced is not severe or prolonged.

In other Western European countries. and in America. though most scientists doubtless impose on themselves the same humane scale of values. there are not the same stringent legal safeguards. It will always happen that the tough-minded and the tender-minded will differ over what constitutes suffering for others. whether humans or animals. and there will thus always be a scatter round the mean of ordinary practice in the conduct of experiments. But there may also be examples at which the average laboratory worker and the ordinary citizen alike revolt, as is shown in our correspondence columns this week. CHARLES DARWIN held that to inflict any pain which is not absolutely necessary deserves " detestation and abhorrence." and all research-workers of integrity subscribe to this judgment. They know that to apply the criterion of necessity calls for unremitting care and attention: but they also know that it can and must be done. Since the pursuit of a new fact can sometimes engross the mind almost completely, they recognise that they must always be on guard: and that wherever their keenness may have impaired their sense of proportion they should seek the help and criticism of colleagues. In the cases cited by our correspondents the essential criterion was not applied.

The Membership

Two years ago an article on Satisfying the Examiner advised M.R.C.P. candidates to:

> Read up to date reviews of medicine and allied subjects. Get the latest copies of *Physiological Reviews*, *Medicine* (Baltimore), the *Quarterly Journal of Medicine*, and other quarterly journals in special subjects. Read *Abstracts of World Medicine*, annotations in *The Lancet*, and the lectures delivered at the college right up to the date of the examination.

So long as examiners felt that they were testing the candidate's fitness to practise immediately as a consultant, quite abstruse questions could be legitimate. But the Royal College of Physicians last week accepted a report (published on p. 252) which states that " membership of the college should signify a knowledge of general medicine that justifies further training as a consultant " and that the examination is best taken early in training. Without proposing radical changes, the report makes valuable recommendations for the conduct of the examination and entry to it. There is no question of lowering its standard; but the clearer definition of its scope. and the other new arrangements. will enable the sound candidate to approach it with more confidence.

Annotations

NEGOTIATION AT LAST

AT the beginning of March the medical journals ceased to accept advertisements from local authorities for public-health appointments. As we explained at the time,[1] this action was taken because the local-authority associations were showing no disposition to enter a Medical Whitley Council and discuss new scales of remuneration for doctors in the public-health service. In the light of the two medical Spens reports, the Society of Medical Officers of Health and the British Medical Association had decided that the revised Askwith scales, as modified in January, 1948, were no longer appropriate; and since the Askwith agreement had thus in effect been terminated we took the view that advertisements could not usefully appear in our columns until negotiations for a new agreement were opened.

For reasons which we mentioned, the local-authority organisations had misgivings about taking any active part in a Medical Whitley Council; and most of them would still prefer the establishment of separate councils. After a meeting last week, however, they told the Ministry of Health that (except for the Scottish associations, whose representatives could do no more than recommend) all of them were

> "prepared to participate in the proposed Medical Functional Council provided that its constitution is so drawn and agreed as to provide for the remuneration and conditions of service of medical practitioners employed by or in contract with local authorities being decided finally by a separate committee without need for confirmation by, but subject to report to, the Functional Council."

This means that the local-authority associations are now willing to enter into negotiations under Whitley arrangements: and, with the rest of the medical press, we are happy to resume publication of local-authority advertisements this week. It is assumed that, as before, the remuneration offered will conform to the revised Askwith scale as modified in January, 1948, and that no distinction will be made between the payment of men and women doctors.

The British Medical Association's draft scales, which will now presumably be brought forward for discussion, were summarised in our issue of Jan. 29.

ELECTRICAL ANÆSTHESIA

THE production of surgical anæsthesia by electrical means has long been an intriguing possibility. It was d'Arsonval in 1890 who first noticed that high-frequency currents could produce anæsthesia, and a great deal of experimental work has since been published on the subject. Longley,[2] of the Burden Neurological Institute at Bristol, has welded this mass of writings together, adding the results of his own experiments. Four well-defined types of anæsthesia can be produced electrically—local, spinal, spinal plus general, and general. Robinovitch[3] was the pioneer of the first; direct current interrupted 100 times a second, with a duration of pulse of 1/1000 sec. is used, both anode and cathode being applied to the nerve-trunks. For spinal anæsthesia either direct or interrupted direct current is applied between the spine and some other part of the body, usually the neck. In animals tonic immobility is produced, but the method did not show great promise in animal experiments and has not been used in man. Spinal plus general anæsthesia is the type produced by Leduc's[4] technique. An interrupted direct current is applied between the loins and the head; animals become motionless and apparently deeply asl
Leduc was so enthusiastic that he submitted him
to such a procedure and recorded his observations.
reported that he became completely paralysed
insensitive to pain, though consciousness was o
dimmed. His colleagues, however, did not carry
experiment to the limits he had intended, and Le
maintained that had they done so complete unc
sciousness would have resulted. General anæsth
is produced by passing a current through the h
and under the name of "electric stunning" this t
nique is commonly used in abattoirs before slaught
the principle is the same as in the electronarcosis t
ment of mental diseases.[5] There is still doubt whe
true general anæsthesia—a reversible and controlla
immobility with loss of consciousness—can in fact
produced electrically. Many workers contend that o
a generalised immobility akin to that of curarisation
obtained, and such criticism is difficult to refute si
relatively few experiments have been conducted
man. It seems likely however that, with the present-d
elaboration and extension of electronic methods, advan
will yet take place in this field.

CONSERVATIVE TREATMENT OF INTUSSUSCEPTION

REDUCTION of an intussusception by pressure of fl
introduced through the rectum has been practis
notably in Australia and Scandinavia, for many yea
It has an obvious appeal, but the fear of rupturing t
damaged gut has discouraged most British surge
from adopting the method. Two recent papers emphas
its relative safety. Nelson,[6] of Sydney, N.S.W., u
the technique elaborated in Australia by Hipsle
In an ill patient the procedure is liable to cause sho
and Nelson advises that it should be carried out und
anæsthesia deep enough to give complete abdomi
relaxation. He also does the reduction in a room ne
the theatre, so that if operation is necessary there w
be no delay. Saline is run into the rectum through
no. 15 catheter passed about 3 in. into the bowel a
retained by a firm grip of the buttocks. The height
the fluid reservoir is 3 ft. As the fluid is introduced
runs at first rapidly and then more slowly. The press
is maintained for 2–3 minutes and the fluid is th
allowed to return. The procedure can be repeated t
or three times. Successful reduction is diagnos
clinically and if there is any doubt it must be confirm
by an exploratory incision at McBurney's point. Wi
this fixed degree of hydrostatic pressure there is said t
be no danger of rupturing the bowel; but Nelson doe
not recommend the method in cases admitted to hospit
more than 24 hours after the onset. In complete
successful cases, the fluid passes the ileocæcal val
and flows into the small intestine. The uniform d
tension of the abdominal cavity which results is the mo
definite sign of reduction. If the fluid is held up
contraction of the ileocæcal sphincter an indefinite swe
ing may be felt in the right iliac fossa, and explorati
through a small incision may be necessary to confi
or complete the reduction. In 102 patients, all und
2 years of age, hydrostatic pressure was used in t
majority as a substitute for or preliminary to operati
In 20 cases the intussusception was reduced witho
operation, and in a further 23 cases it was found reduc
at operation. Of the 10 patients who died, only 4 we
treated within 24 hours of onset; the remainder we
not admitted to hospital until 32 hours to 3 days af
onset.

Lindberg and Morales,[8] of Norrköping, Swed
describe afresh the Scandinavian method in whi

dio-opaque enema is given and the intussusception duced under direct vision on the fluorescent screen. examiner controls the flow of the medium by means clip on the rubber tubing and the height of the rvoir is about 5 ft. They have used 'Pharmabaryt' % barium sulphate and 2% indifferent colloids) an opaque medium. The immediate effect of the l is to stimulate the colon to contract and push back enema. The flow is stopped until the bowel relaxes is then renewed. Reduction is judged complete only n the fluid is seen to flow freely into the small intestine. far as possible manual reduction is avoided; but if, often happens, a lump the size of a walnut can still be in the cæcal region, the cæcum is held in one hand and sage performed upwards with the other. In 3 of the consecutive cases reported reduction was still incom- e, and the procedure was repeated under general esthesia, but all 18 were successfully reduced in the . In other cases operation has occasionally been orted to, and no complication from the enema treat- nt has ever been found on opening the abdomen. dberg and Morales attribute their success largely to early stage and good condition in which the patients re referred to hospital. Their patients were all under years of age, and they believe that reduction by ma is easier in very young children.

Considering the good results obtained by early opera- n in intussusception, it is understandable that surgeons itate to adopt any method of treatment that will nd between the patient and immediate laparotomy. t if preparations for operation are made before- nd and the procedure is carried out in or near the eatre, a trial enema will scarcely delay operation at all, d under these circumstances Hamilton Bailey[9] recom- nds its wider use. The opaque enema seems more isonable than the blind introduction of saline.

THE LOCK HOSPITAL

THE controversy over the closure of the Lock Hospital ludes two separate issues, tactical and strategic. n the tactical level the question is simply whether the edical interests of the inhabitants of London are best rved by maintaining a hospital in Soho for the treat- ent of venereal diseases, or by using its premises for urological cases for which there is a shortage of beds. is is exactly the sort of problem that the regional spital boards were set up to solve, so that our hospitals all be used to full advantage; and they must not be evented from doing their duty by the fact that all such cisions are bound to cause pain to doctors who have orked for "redundant" hospitals and patients who ve been in the habit of attending them. We cannot lp thinking, however, that the North-Western Regional ospital Board, in making and reaffirming its decision, is been influenced by the strategic argument that nereology is, or is rapidly becoming, an obsolete ecialty, and that special hospitals for venereal diseases e outmoded. How far is this argument sound? There is always been something odd about linking two such verse diseases as syphilis and gonorrhœa merely because ey are spread by the same means: the one seemed to long to urology and the other to internal medicine; d now that both are so vulnerable to chemotherapy any believe that the time has come to stop segregating em and the doctors who treat them. This view is rongly contested, however, by venereologists, who elieve that venereal diseases, presenting special psycho- gical and epidemiological problems are well treated only by eople who study them intensively: they say, with good eason, that treatment with antibiotics is at a stage when uch knowledge and good judgment are required,[10] nd they very rightly point out that venereal diseases are still doing enormous damage at home and abroad. It is for these reasons that thirteen teachers of venereology, writing in the *Times* of July 27, plead that London should have a centre for postgraduate teaching and research to provide the trained men and women still needed in this specialty, especially in Colonial territories: and they urge that the Lock Hospital should be used for this purpose. On this strategic level it is by no means easy to accept the decision of a regional board as final, unless at least it is known to have the concurrence of the authorities concerned with postgraduate education and the needs of the medical services overseas.

DOMICILIARY CARE IN OXFORDSHIRE

THE idea of bringing hospital care into the home has much to recommend it. Many old people and chronic sick, who when they are admitted to hospital are likely to occupy beds for long periods, are particularly well suited for home care. A scheme for providing such care was lately started by Addenbrooke's Hospital,[1] Cambridge; and St. Helier Hospital, Carshalton, has a scheme for the home care of old people. Now the Oxford regional hospital board hopes to launch at Swindon a more extensive experiment. Dr. John Lowe, chairman of the chronic-sick subcommittee of the board, is to make a pilot survey of institutions in the region and has already analysed the cases in St. Margaret's Hospital and Welfare Home at Stratton, of which he is medical superintendent.

The hospital and home are joint users of premises which were originally a public-assistance institution, part of which has been taken over by the public-health department. The hospital has 236 beds, 108 of them for chronic cases; and the welfare home takes 150 residents. The hospital is under the Swindon and district hospital management committee, while the home is under the Wiltshire county welfare committee, who, it is hoped will help to operate a joint scheme. One part of the plan is to increase the number of beds for the chronic sick by exchanging the welfare home with the isolation hospital. The 80 beds in the isolation hospital are seldom used, and it is felt that these would suffice for a residential home, provided a scheme of domiciliary care was arranged at the same time. The 150 beds in the present country home would better serve the needs of patients who must have active medical or nursing care.

The crux of the whole plan of course is the domiciliary scheme. This, the board point out, must integrate the arrangements for the chronic sick under the various parts of the Act. Chronic sick in hospital come under the regional hospital board; those in house, residential home, or hostel, under the local authorities, who are also responsible for health visiting, home nursing, care and aftercare in illness, and domestic help; while general-practitioner service to the patient at home comes under the executive council. The board suggest that all these services might be integrated under a new officer, a senior clinician, who would work in close touch with the medical officers of health, the general practitioners, the "four aitches" (home, hospital, residential home, and hostel), and the various voluntary organisations. He would be on the staff of the general hospital and responsible for inpatient treatment. Under such a system appropriate cases could be given priority on medical and social grounds; and when a patient was discharged from hospital continuous care could be arranged for him, whether he went to his own home or into a residential home or hostel. Complete responsibility for the chronic sick would thus come under a single organisation, and the care given would include the services of the almoner, health visitor, district nurse, and home help: the loan of hospital equipment when necessary; and special arrangements for catering, laundry, and transport. The board also hope to set up special clinics for old people, for the diagnosis and early treatment of degenerative conditions. Dr. Lowe's analysis of the 138 patients now in the welfare home shows that they are there largely for social reasons—because they are widowed, or have lost their homes, or are awaiting a council house. Of the 36 women and 71 men in St. Margaret's Hospital nearly all need treatment, and there is a long waiting-list. The new scheme should ensure better care for far larger numbers. We wish it every success.

PITUITARY EXTRACT IN RADIOLOGY

Intestinal shadows militate against good X-ray pictures of the gall-bladder and kidney. In 1936 Collins and Root[1] recommended the use of 'Pitressin,' the pressor principle of the posterior pituitary, to stimulate bowel activity and hence aid in the elimination of gas. Since then pitressin has been widely used by radiologists to prepare patients for cholecystography and pyelography. In some countries this is apparently done as a routine, but here the procedure is normally reserved for cases where gas shadows have actually obscured the diagnosis in preliminary films. Mills and others[2] have lately reported two instances of prolonged myocardial ischæmia and two sudden deaths that have occurred at the Mayo Clinic after the use of pitressin for this purpose. They consider that there was a causal relationship between the administration of the drug and the untoward incidents and recommend that it should only be employed with the utmost discretion. Minor unpleasant reactions to pitressin are familiar and have been reviewed by Kirklin and Seedorf.[3] These include nausea, faintness, and abdominal cramps; but in spite of its wide and varied use over many years there has been only one previous account of a serious reaction, and this followed a water-pitressin test for epilepsy.[4] It is well known that pitressin is a powerful vasoconstrictor of the coronary arteries,[5] and in patients with coronary disease changes in the electrocardiogram similar to those of anoxia have been produced.[6] In view of these changes Ruskin[7] suggested the injection of pitressin as a test for latent coronary insufficiency and in particular to differentiate angina pectoris from other chest pains. He found a close parallelism with the exercise-tolerance test but did not advise the general adoption of his pitressin test because of possible side-effects. In his patients the only reactions were gagging, occasional slight vomiting, slight abdominal cramps, or an uncontrollable desire to pass urine or fæces.

Before condemning the pitressin technique of gas-removal, which has a definite if limited place in radiology, it would be well to examine the evidence in detail. Pitressin has been used in tens of thousands of cases and this is the first warning which has appeared. The Mayo Clinic cases are not altogether convincing, and the writers of the report themselves studied the E.C.G. changes after pitressin in 100 consecutive patients without finding any reaction or significant abnormality. Of their four possible examples of severe reactions, the first patient experienced substernal pain of ischæmic type $1^{1}/_{2}$ hours after the injection of 1 ml. (10 pressor units) of pitressin. The pain recurred on and off during the next 8 days and was followed by a severe attack on the 11th day with E.C.G. changes of infarction. He quently recovered. The second patient died at hours after the injection, and necropsy showed coronary sclerosis with evidence of old occlusion recent infarction. The third patient was found 20 minutes after his injection, but there was no mortem examination. An E.C.G. taken 2 days befo shown multiple ventricular extra-systoles but no abnormality. The fourth patient had previously s from angina and collapsed 4 hours after his inj The E.C.G. taken subsequently did not reveal any c teristic pattern of infarction, but he died on the 8t during an attack of pain, and terminal vent fibrillation was recorded. Necropsy showed evide old but not recent infarction. Reactions to pit usually occur within a few minutes of the injectio Ruskin noted that E.C.G. changes produced by pit as a test for coronary insufficiency occurred within minutes and reverted to normal within 10–15 mi It may therefore be doubted whether the reactio the Mayo Clinic cases were necessarily due to the tion, though the possibility cannot be ignored. Pe the wise conclusion is that pitressin should not be as a routine but only when specifically indicated, an in patients known to have had ischæmic pain or evi of coronary disease. There are other simple metho dealing with gas.

GIFT FOR ORTHOPÆDICS AT OXFORD

Lord Nuffield has given £50,000 to the Nuffield O pædic Centre at Oxford. The centre has two responsibilities—first, the treatment of its patien the Wingfield-Morris Orthopædic Hospital; and seco postgraduate training. The gift is to be put at disposal of trustees for the use of the centre. fund will not relieve the regional hospital board an university of their obligations to the hospital and department; but it will enable the centre to offer sp facilities to the orthopædic surgeons and postgrad students who come from all parts of the Commonwe

COMMITTEE ON HOSPITAL ADMINISTRATI

The Central Health Services Council has appoi a committee:

(1) To review the organisation of the hospital ser under the National Health Service Act, 1946, but not ma concerning the administration of individual hospitals, an make recommendations;

(2) To frame detailed terms of reference for a commi on the administration of individual hospitals.

The members are: Mr. F. Messer, M.P., chairman the council (chairman); Sir Harold Wernher (v chairman); Mr. E. C. F. Bird; Alderman Bradb Mr. F. J. Cable, F.H.A.; Sir Allen Daley, F.R.C Mr. S. C. Fryers, F.H.A.; the Hon. A. J. P. Hov M.P.; Mr. R. A. Mickelwright, F.H.A.; Sir Owen M head; and Dr. W. G. Patterson. The joint secretaries Mr. E. J. S. Clarke and Mr. E. W. Bryant of the Mini of Health.

Dr. T. Stacey Wilson, consulting physician Birmingham United Hospitals, died on July 30, at age of 80.

Dr. J. M. Mackintosh has resigned his appointn as dean of the London School of Hygiene and Trop Medicine as from the end of this year. He will conti to occupy the chair of public health at the school.

We understand that a committee formed jointly the Institute of Professional Civil Servants, the Mini of Health Medical Staff Association, and the Bri Medical Association has submitted to the Treas proposals for revision of the scales of salary of med men and women in the Civil Service.

Points of View

THE DOCTOR'S PROFESSION*

1. The Doctor as Technician

many doctors—and their number includes some might claim to be Christians—the profession edicine is essentially the practice of a technique or , operating along well-recognised lines. In so far as moral considerations arise in it, they are concerned with the doctor's faithfulness to the laws of his nique, of which he is the best judge. Why trouble member of an already overworked profession with ters which are both extremely complicated and emely controversial in themselves and make no rence anyway to 99 out of 100 decisions which the age doctor has to make ?

his attitude needs careful examination, even though ay be held very confusedly by some of its exponents. use up to a point there is obviously a great deal of h in it. It is clear that a large amount of medical tice is a matter of the application of a technique ch can be learnt in fundamentally the same way as t of, say, an engineer. Doctors are practical men, have learnt a method of treating disease based on ory-taking and the eliciting of physical signs, and en the results of this examination) who possess a ly distinct system of actions appropriate to the result the examination. It is not too much to call this a chnique," as indeed anything which is the object of ctice and experience is bound to become. To expect octor, every time he is faced with a case of coronary ombosis, to recapitulate in his thinking the whole elopment of the profession's views about the disease, idiculous ; he is bound to put into practice for the st part the rules of treatment which he learnt as a dent and which he has modified in his own experience. en the "bedside manner" in its best form must be nitted to be largely a "technique": few doctors uld care to maintain that their thoughts about their tients are perfectly represented by their manner! is is not to say that this is wrong—on the contrary it obviously a great advantage if a doctor can economise energies by diverting as much of his activities along ple routine lines as possible. All we are concerned to intain for the moment is that the doctor can be arded as practising a technique, and, in that sense ly, can be regarded as a "technician."

MORE THAN A TECHNICIAN ?

Thus far there is little cause for disagreement. The vergence appears, of course, when it is asserted that e doctor need not consider himself as being anything re than a technician. Here, not only the Christian t, as we shall see, the classic tradition of medical actice itself, must take issue with the doctor-technician.

There is some difficulty in defining this attitude. though it has obvious affinities with philosophical turalism, it is not so precise as that and has had no herent exposition in the history of medicine. For that atter, there have been very few philosophers of medicine any kind since Sir Thomas Browne. But even if it generally undefined and implicit, this is nevertheless a idespread and formidable attitude in the profession today. It is that of the doctor who prides himself on his practicality and on being more interested in what he can do now on the strictly medical level than in what he would describe as vague and often irrelevant issues. It also makes such a doctor assume, whether consistently or not, that, while genetic and social and psychological and economic factors may have a right to be considered in medical practice and education, moral and spiritual factors can safely be ruled out and that they need be no concern of his. Indeed, he often suggests that it is an unwarrantable interference with the autonomy of the profession to suggest that they have, especially if the suggestion comes from the clergy.

It is worth examining this attitude closely, even if it is undefined, because, as in a practical working philosophy, it appears to be the only serious rival to the one maintained in these essays. (Socialist medical thought, which might be considered from some points of view to offer itself as yet another influential medical philosophy, can hardly claim to be that, as so far it has concerned itself simply with suggesting specific ways in which the organisation of medical research and practice might be improved.) It is important also that full justice should be done to this attitude, and that for two reasons. The first is that those who hold it strongly suspect Christians of special pleading in relation to it and of being more concerned to prove the relevance of their peculiar beliefs to medicine than to deal faithfully with all the facts. The second reason is that, as we have already recognised, up to a point there is a great deal of justice in the view that the doctor is primarily a technician, and it is important for their own understanding of the medical vocation that Christians should make full allowance for it.

First, then, let it be freely recognised that no-one wishes to assert that medical technique is anything but a highly complicated one. No-one would want to assert that the doctor's work is on a level with that of a garage-hand or that the human constitution can be as easily handled as a motor-car. All that is claimed is that, although the responsibility of the doctor to the patient may be infinitely greater in degree than that of the garage-hand to the car, it is not ultimately radically different in kind. That there is a substantial element of truth in the claim is obvious.

Secondly, it does not follow that the doctor who maintains that he is no more than a technician necessarily holds his profession in low esteem or is prompted only by motives of personal advancement. The reverse is often the case. It is true that it is possible to attain to considerable wealth and prestige through the practice of medicine, but it is far from being the easiest of roads open to those whose primary goal is to get rich and famous quick. Every doctor has to undergo a long and exacting training, and the outstandingly successful doctor is rarely able to achieve his eminence by any other means than those of exceptional ability and disciplined application under the constant eye of intensely critical colleagues. Even the laziest and most indifferent person who strays into medicine cannot escape performing a considerable amount of skilled and useful work and accepting heavy responsibilities under conditions of frequent inconvenience and unpleasantness. Any criticisms made of the attitude of some doctors towards their profession must be tempered, therefore, by a generous recognition that even if they do regard themselves only as technicians they are technicians of a very high order, bearing peculiarly arduous technical responsibilities.

Nor, thirdly, need it be maintained that the doctor who regards himself primarily as a technician is a philistine. He may see himself as a humble partner in a great enterprise of coöperative research and practice, grateful for the inspiring privilege of belonging to a profession which has produced so many great men and

---

Four essays arising from discussions held under the auspices of The Christian Frontier Council (8, The Cloisters, Windsor Castle). For permission to print them we are indebted to the Student Christian Movement Press Ltd. (58, Bloomsbury Street, W.C.1) which is shortly publishing them in full, with others, under the title *The Doctor's Profession*. This book is likely to appear in October, and the probable price is 4*s*. 6*d*.

so many beneficent discoveries and which has achieved such a high degree of skill in the fulfilment of its technique. There is not necessarily any lack of very high professional standards along certain lines among those who take this attitude. This becomes the more clear when it is borne in mind that most medical advance has been made largely under the impetus of the development of the profession itself rather than through any outside agency. It is incorrect to assert, as some unsympathetic partisans do, that medical advances have been made only in the teeth of ecclesiastical obscurantism, but it can hardly be claimed, on the other hand, that many of them are the direct result of Christian inspiration. A very good case can be made out, as Prof. A. N. Whitehead has shown in *Science and the Modern World*, for the claim that modern science itself could only have arisen out of a Christian attitude towards life which believed in the rationality of the universe; but it has to be allowed that that is not a truth which is immediately obvious to a busy technician who has little knowledge of cultural history and who takes things as he finds them today.

Fourthly, the doctor-technician will argue that in medicine knowledge is more important than good intentions. This has always been so and it becomes increasingly true as medical science advances and as a cure comes to depend more and more upon an accurate diagnosis rather than upon incalculable fortune. Surely, therefore, it is more important that the limited mental energy of the doctor should be spent on acquiring this ever-expanding body of knowledge than on pursuits of dubious usefulness which are extraneous to his work. The man who reads theology and exercises himself over religious matters is likely to be diverted from giving his full energy to reading medicine and concerning himself with his patients. The frequency with which the advice is given to the young doctor to concentrate on his work and marry late indicates how difficult it is for the man of average ability to do anything apart from his work with any degree of serious application. Why jeopardise one's professional chances and possibly damage one's technical competence by introducing powerful and distracting non-professional influences like religion into one's work? This may seem to the Christian to beg the question both of the real nature of knowledge and the precise character of religion (is it primarily a matter of good intentions?) but it is certainly a widely held point of view, which demands to be met.

LIMITING RESPONSIBILITIES

On a deeper level, it may be contended that so far as any ethical decisions are required in actual practice, they are the patient's own concern, and it is an intolerable burden that they should be wished on to the doctor. To do so is likely to place the doctor in complicated situations he would do well to avoid. Besides, ethical decisions taken by the doctor must frequently involve not merely a refusal to take a certain line of action but a decision to take a definite line of action and to persuade the patient to take it also. Thus the doctor changes from disinterested servant to active propagandist, with obvious dangers to the confidence with which he can be regarded by the patient. This is undoubtedly a consideration of great weight. The doctor can very easily persuade himself that he knows what is good for the patient in all branches of his life and assume that he, the great healer, has dictatorial powers over the patient. The reverence in which the doctor is held by some patients and their readiness to depend upon him makes this all the more dangerous.

Nevertheless, the way to overcome this danger is not simply to pretend that the personal factor, with all its moral and spiritual implications, does not exist in medicine. The doctor-technician can hardly cons *maintain that the personal factor is of no* acco he has a constant interest in minimising its impo And because he refuses to admit that he need ha clearly defined principles to guide him in this rea deals with any moral and spiritual issue either uncritical acceptance of conventional standards doing what is most convenient and least troubleso himself. Thus he is able to persuade himself tha is no relationship which is likely to arise in his w which he will not be able to work out a technique will allow him to negotiate it without undu commitment. His ideal, even though he ma prepared to admit that in an imperfect world h not always be able to reach it, is to achieve a mec simplicity and objectivity in dealing with his pati

THE CLASSIC TRADITION

It must be emphasised in the strongest possible that this attitude is wholly opposed to the classi ception of medical practice. The Hippocratic O no longer taken by doctors on qualification i *country, but it is regarded as the representative* ex of the medical ethical standard. The Hippocratic runs:

> I swear by Apollo, the physician, and Æsculapiu Health, and All-heal, and all the gods and goddesses according to my ability and judgment, I will keep thi and this stipulation—to reckon him who taught m Art equally dear to me as my parents, to share my su with him, and relieve his necessities if required; t upon his offspring in the same footing as my own br and to teach them this art, if they shall wish to le without fee or stipulation; and that by precept, l and every other mode of instruction, I will impart a kno of the Art to my own sons, and those of my teacher to disciples bound by a stipulation and oath accord the law of medicine, but to none others.
>
> I will follow that system of regimen which, accord my ability and judgment, I consider for the benefit patients, and abstain from whatever is deleteriou mischievous.
>
> I will give no deadly medicine to any one if aske suggest any such counsel; and in like manner I wi give to a woman a pessary to produce abortion.
>
> With purity and with holiness I will pass my lif practise my Art.
>
> I will not cut persons labouring under the stone, bu leave this to be done by men who are practitioners o work.
>
> Into whatever houses I enter, I will go into them f benefit of the sick, and will abstain from every volu act of mischief and corruption; and, further, fro seduction of females or males, of freemen and slaves.
>
> Whatever, in connexion with my professional prac not in connexion with it, I see or hear, in the life o which ought not to be spoken of abroad, I will not di as reckoning that all such should be kept secret.
>
> While I continue to keep this Oath unviolated, m be granted to me to enjoy life and the practice of the respected by all men, in all times! But should I tr and violate this Oath, may the reverse be my lot!

Most of the first sentence and the fifth are, of co profoundly different in their application now. Bu regarding these, what of the remainder is left, medicine has no sanction outside itself, when thera abortion and terminal narcosis are permissible, "pure" and "holy" are epithets far less esteem the profession than "courageous," "distinguished "prosperous"? The indenture of the doctor-techn runs, one might say:

> I will practise medicine according to my ability judgment. I will produce abortion, expedite death, kill the newly born when it is medically desirable. respect the confidence of my patients, and will adhe society's conventions in my relations with them. *If I su* in these undertakings I expect to be prosperous and respe if not, to be a failure and struck off the register.

is is something of a caricature ; yet the contrast is ient to illustrate the point we wish to make—that cine on these terms is inadequate medicine.

THE CHRISTIAN ATTITUDE

this matter, as may be expected, the Christian take his stand on the classic tradition of medicine condemn the inadequacy of the doctor-technician's oach. At the same time, it is unfortunate that there little that, as yet, can be said from a Christian point iew which speaks directly to the attitude of the or-technician. It is true that he is often aggressively udiced in his consideration of the contribution of the stian faith to medicine. In particular, to claim, as requently does, that the Church has retarded the nce of medical science is very hard to justify. The ch has said very little in any official way about nce in medical science, except on certain subjects re the extent to which new developments in medical tice, such as the use of abortion and sterilisation, be allowed to be at least problematical. If occa- ally clerics have in the past attacked any new develop- ts, such as the use of anaesthetics, they have not more vocal than conservative groups in the profes- itself at the time. The irritation of hostile doctors be due, however, to the fact that they are either oyed by the superior attitude taken up by Christians hat they are disappointed that Christians have not n them very much help in an enterprise where they eve they may reasonably expect help. Too often, istian comment on medical issues is either so general- as to be vague and unconvincing or else so closely ted to a specific issue that those who do not approach ith Christian preconceptions cannot see why such a is made about it.

ore serious, however, is the complaint that Christian ment has been too often negative. The Christian ics of the doctor-technician fasten on his active ngdoing rather than upon his sins of omission. It is, ourse, easier to criticise in the light of preconceived ndards than to indicate where the profession might more good were its function not so narrowly con- ed. Yet it is precisely here that the most devastating istian criticism of the notion of the doctor-technician be found.

hus, it is surely becoming increasingly clear that the tor-technician, in trying to contract out of the moral onsibilities which medical practice necessarily entails, ying in the face of the plain facts. The experience of scientific technicians in relation to the discovery of mic power is a lesson to all who work in the same l. There is no greater illusion than that which umes that men can safely be content to produce their ults without a thought for their consequences in the of the world where we all, including the technician self, live and seek well-being. Medicine has not yet its atomic bomb, although the doctor has long been iliar with how great a power of life and death rests h him. When the doctor contemplates the develop- nt of his own research along the lines of bacteriological rfare, radioactive gases, and genetic control, can he iously believe that either the profession itself or iety in general will allow him to pursue his way dless of any responsibility for his actions ?

AVOIDING MORAL ISSUES

The doctor-technician, in fact, makes the naïve umption that the development of scientific knowledge always good in itself, and that, if left to take its own y, it will always necessarily lead to good ends. But entific technique, although it is the product of a inite moral attitude and encourages in those who ploy it certain moral attitudes, is itself morally utral and can be employed for good or bad ends. The fact that, in the history of medicine, it has been used for quite conspicuously beneficial ends, is no guarantee that it always will be so used. The Christian understanding of human corruption prompts men to realise that they dare not take the moral foundations of their profession for granted and that the fact that something is now in reputable hands does not mean that it always will be. Almost anything that the human mind has ever envisaged as possible, no matter how devilish, has been attempted.

The doctor-technician fails also to realise how radically he is conditioned by his environment in trying to contract in the way he does out of the realm of moral decision. All he does, in fact, is to make himself "the sport of every wind of false teaching" and the perfect instrument for the meek fulfilment of the wills of strong men who are the enemies of humanity. What precise arguments would the doctor-technician use against an order from Adolf Hitler to exterminate the Jews and to make prisoners-of-war endure torture to make an interesting experiment ? Will the tacit acceptance on the doctor's part of standards of morality and integrity current in society around him be sufficient to give him standing-ground to resist attempts to force him to take action which makes far sharper attacks on his scientific disinterestedness than anything which over-zealous moralists might ever suggest ? Knowledge is power, it is true, but as Karl Jaspers pointed out in a striking rectorial address on the reopening of the medical faculty of Heidelberg University in 1945,[1] it is not necessarily power to those who discover it. As the atomic scientists have found out, powerful knowledge is a dangerous secret to carry around with you when there are desperate characters who also possess political power about, and the one who possesses such a secret needs to know very clearly what his own standards are if he is to prevent its exploitation for ends he would deplore.

TECHNIQUE OF A SPECIAL ORDER

At the same time, the Christian should do full justice to the delicacy of this issue as it confronts the doctor. As has already been sufficiently emphasised, there is a sense in which the doctor is a technician, who can be satisfied simply with providing those who call upon him with efficient technical service and leaving it at that. A due realisation of his place as a technician on the doctor's part may frequently act as a protection to the patient against unwarrantable inroads on his privacy and liberty by the doctor. It would be tiresome indeed if all doctors used visits by busy patients for treatment for sprained ankles as occasions for searching probes into the state of their souls. Likewise, the Christian needs to insist on the importance of technical competence on the strictly scientific level. No amount of personal devotion or theological learning can make up for medical ignorance on the doctor's part.

The doctor is a technician ; but because he deals, not with machines, but with human beings, his technique is of a different order from that of the usual scientific technician. Here the Christian teaching about the uniqueness of each individual comes into play. Any method of handling patients can lose its spontaneity and individual insight and become no more than a technique, and it can happen with busy Christian doctors as easily as with anyone else. But what the Christian sees with exceptional clarity is that the technical considerations which must and should enter into his relation with his patient never finally exhaust that relationship. The patient's physiology, psychological make-up, and social and economic environment all have their part in helping the doctor to understand him, but ultimately it is the individual in his mysterious personal uniqueness with whom the doctor has to deal.

---

[1] *Christian News Letter*, No. 247, Nov. 14, 1945.

so many beneficent discoveries and which has achieved such a high degree of skill in the fulfilment of its technique. There is not necessarily any lack of very high professional standards along certain lines among those who take this attitude. This becomes the more clear when it is borne in mind that most medical advance has been made largely under the impetus of the development of the profession itself rather than through any outside agency. It is incorrect to assert, as some unsympathetic partisans do, that medical advances have been made only in the teeth of ecclesiastical obscurantism, but it can hardly be claimed, on the other hand, that many of them are the direct result of Christian inspiration. A very good case can be made out, as Prof. A. N. Whitehead has shown in *Science and the Modern World*, for the claim that modern science itself could only have arisen out of a Christian attitude towards life which believed in the rationality of the universe; but it has to be allowed that that is not a truth which is immediately obvious to a busy technician who has little knowledge of cultural history and who takes things as he finds them today.

Fourthly, the doctor-technician will argue that in medicine knowledge is more important than good intentions. This has always been so and it becomes increasingly true as medical science advances and as a cure comes to depend more and more upon an accurate diagnosis rather than upon incalculable fortune. Surely, therefore, it is more important that the limited mental energy of the doctor should be spent on acquiring this ever-expanding body of knowledge than on pursuits of dubious usefulness which are extraneous to his work. The man who reads theology and exercises himself over religious matters is likely to be diverted from giving his full energy to reading medicine and concerning himself with his patients. The frequency with which the advice is given to the young doctor to concentrate on his work and marry late indicates how difficult it is for the man of average ability to do anything apart from his work with any degree of serious application. Why jeopardise one's professional chances and possibly damage one's technical competence by introducing powerful and distracting non-professional influences like religion into one's work? This may seem to the Christian to beg the question both of the real nature of knowledge and the precise character of religion (is it primarily a matter of good intentions?) but it is certainly a widely held point of view, which demands to be met.

LIMITING RESPONSIBILITIES

On a deeper level, it may be contended that so far as any ethical decisions are required in actual practice, they are the patient's own concern, and it is an intolerable burden that they should be wished on to the doctor. To do so is likely to place the doctor in complicated situations he would do well to avoid. Besides, ethical decisions taken by the doctor must frequently involve not merely a refusal to take a certain line of action but a decision to take a definite line of action and to persuade the patient to take it also. Thus the doctor changes from disinterested servant to active propagandist, with obvious dangers to the confidence with which he can be regarded by the patient. This is undoubtedly a consideration of great weight. The doctor can very easily persuade himself that he knows what is good for the patient in all branches of his life and assume that he, the great healer, has dictatorial powers over the patient. The reverence in which the doctor is held by some patients and their readiness to depend upon him makes this all the more dangerous.

Nevertheless, the way to overcome this danger is not simply to pretend that the personal factor, with all its moral and spiritual implications, does not exist in medicine. The doctor-technician can hardly co maintain that the personal factor is of no acco he has a constant interest in minimising its im And because he refuses to admit that he need clearly defined principles to guide him in this deals with any moral and spiritual issue eith uncritical acceptance of conventional standar doing what is most convenient and least trouble himself. Thus he is able to persuade himself t is no relationship which is likely to arise in his which he will not be able to work out a techniq will allow him to negotiate it without und commitment. His ideal, even though he prepared to admit that in an imperfect world not always be able to reach it, is to achieve a m simplicity and objectivity in dealing with his pa

THE CLASSIC TRADITION

It must be emphasised in the strongest possib that this attitude is wholly opposed to the cla ception of medical practice. The Hippocratic no longer taken by doctors on qualification country, but it is regarded as the representative of the medical ethical standard. The Hippocra runs:

> I swear by Apollo, the physician, and Æscula Health, and All-heal, and all the gods and godde according to my ability and judgment, I will keep and this stipulation—to reckon him who taught Art equally dear to me as my parents, to share my with him, and relieve his necessities if required; upon his offspring in the same footing as my own and to teach them this art, if they shall wish to without fee or stipulation; and that by precept, and every other mode of instruction, I will impart a k of the Art to my own sons, and those of my teac to disciples bound by a stipulation and oath acco the law of medicine, but to none others.
>
> I will follow that system of regimen which, acco my ability and judgment, I consider for the benef patients, and abstain from whatever is deleteri mischievous.
>
> I will give no deadly medicine to any one if as suggest any such counsel; and in like manner I give to a woman a pessary to produce abortion.
>
> With purity and with holiness I will pass my practise my Art.
>
> I will not cut persons labouring under the stone, leave this to be done by men who are practitioner work.
>
> Into whatever houses I enter, I will go into them benefit of the sick, and will abstain from every v act of mischief and corruption; and, further, f seduction of females or males, of freemen and slaves
>
> Whatever, in connexion with my professional pra not in connexion with it, I see or hear, in the life which ought not to be spoken of abroad, I will not as reckoning that all such should be kept secret.
>
> While I continue to keep this Oath unviolated, be granted to me to enjoy life and the practice of respected by all men, in all times! But should I and violate this Oath, may the reverse be my lot!

Most of the first sentence and the fifth are, of profoundly different in their application now. I regarding these, what of the remainder is left medicine has no sanction outside itself, when ther abortion and terminal narcosis are permissible "pure" and "holy" are epithets far less estee the profession than "courageous," "distinguish "prosperous"? The indenture of the doctor-tec runs, one might say:

> I will practise medicine according to my abili judgment. I will produce abortion, expedite dea kill the newly born when it is medically desirable. respect the confidence of my patients, and will ad society's conventions in my relations with them. If I in these undertakings I expect to be prosperous and res if not, to be a failure and struck off the register.

esides demanding hospital experience, the college go further and refuse to recognise particular posts ining purposes unless they satisfied certain criteria, d exert strong influence to improve the educational of such posts. On the other hand, criteria of this ould not be applied consistently to hospitals in the ions and Colonies and in foreign countries; and y, 1948, no fewer than 128 entries were from as.

things now stand, though candidates have not spent a year as resident in a major hospital, ave usually had considerable experience. Of the 596 lates last July [1948], only 16 were under twenty- ears of age. Of the 314 ex-Service candidates, t least two years' military service, all but 14 had hospital post before joining up; and of the ing 282 candidates, 212 had done more than two postgraduate work in hospital.

balance, the committee feel that, for the present, ollege should not specify any particular kind of ence as a condition of entry to the examination. is conclusion their lesser reason is that the claims Services make it hard for many to follow a fixed mme; their greater, that restrictions ought to be ed unless patently necessary. Especially would esitate to place any new obstacle in the way of the ble minority who approach consultant status by unconventional path; the physiologist and the al practitioner, for example, should not be denied, gulation, the chance to show their fitness to become al registrars. Also the committee reject the tion that the candidate should be allowed to testimonials to his merits: for this would expose amination to suspicion of prejudice. They believe, ver, that in doubtful cases it would be useful for xaminers to have full information of past employ- . On entry, candidates should be asked to give ls of the appointments they have held, and also to nate a referee who (on request) could say exactly work these appointments have involved.

PRIMARY EXAMINATION

e committee were not persuaded that it would be to precede the membership examination by a ary examination in anatomy and physiology, or her subjects. If this were taken before the student ed the wards, its relevance to the final examination d be small; and if it were taken at a time when the idate is mainly concerned with clinical problems ould probably promote cramming rather than the ed broadening of fundamental knowledge. No ber of the committee wished to set another examina- l hurdle across the course of the consultant's training.

CONDUCT OF THE EXAMINATION

ten Papers

ere are two papers, of three hours each. The first medical anatomy and the principles of medicine; econd is on the practice of medicine, the principles ublic health, and psychological medicine. The mittee think that the papers as nowadays set are fitted to test the knowledge of candidates of registrar s, but they would like to see more questions asked pplied physiology and applied pharmacology. It suggested that candidates should be offered a choice uestions, but the committee deemed this inappro- te in an examination designed to test basic rather specialised knowledge. However, if all questions to be answered, it follows that examiners must be tantly careful to keep them within the general range. n objection to an examination of the basic type is the man with exceptional competence in some icular branch of medicine has little chance to display The committee were attracted by a proposal that, des answering the obligatory questions, the candidate ld have to write an essay, which would show what he could do with a congenial topic. (This introduction of an essay would incidentally be a symbol of the college's belief that doctors should be capable of expressing themselves in cultivated English.) But the practical difficulties of the proposal are very real. If the candidate chose any subject he liked, or if the choice offered were large, it might become usual to prepare an essay in advance. If, on the contrary, the choice were small, the candidate might find no subject to his taste. Foreigners would generally be placed at a disadvantage, which would have to be taken into account; it would be hard to lay down criteria on which the essays should be marked; and the existence of a special essay paper might deter the censors from setting questions that need an answer in essay form, as has lately been their practice. For these diverse reasons, the suggestion was abandoned.

It was agreed that translations from French and German should be retained in the examination, though no additional time should be assigned them. Besides providing evidence of general education, they enable examiners to give credit to candidates who will be able to expand their knowledge of medicine by reading in these languages.

Clinical

By common consent the clinical part of the examination is the most important; and it is here that criticism is strongest. In brief, it is said that too little time is allowed for examining the patients; that success depends too often on being fortunate in one's cases and one's examiner; that the results are correspondingly less predictable than those of other examinations; and that, on the whole, young candidates full of facts do better than the more mature.

Even if held by archangels, an examination rejecting so high a proportion of candidates would certainly be attacked by some of the hundreds disappointed each time, and by some of their teachers. The critics do not always endorse each other's criticisms, and many good judges seem to be satisfied with the present examination as a searching test of competence. All examinations include an element of luck, and on the evidence before them the committee are not convinced that the results of this one have been more than ordinarily unpredictable. Nevertheless, they recognise that it has latterly been conducted under great difficulties, and they feel that the grounds for criticism can and should be diminished.

At present candidates have forty minutes in which to examine a "long case," and are then questioned on it for fifteen minutes by one censor: after which they spend fifteen minutes with another censor who questions them on "short cases." The maximum of marks obtainable is 80 for the long case and 40 for the short ones, and a minimum of 70 marks must be obtained. Obviously, failure in the single long case usually spells failure to obtain the membership, and some of the committee felt that it would be easier to assess the candidate's performance if he examined two long cases of different kinds and if he could make his investigations without the sense of haste imposed by a time-limit of forty minutes. They were impressed, however, not only by the practical difficulties of doubling the number of long cases, but also by the argument that a good examiner needs no more than one case, of any kind, to tell him how the candidate sets about his work. The examination is meant to test method at least as much as knowledge; and, if it puts a premium on readiness of judgment, that is defensible because this quality is useful to consultants. A former censor has declared that "in the routine and method of examining a patient, and in the recognition and evaluation of obvious physical signs, the candidate must be right first time."

The committee cannot escape the conclusion that, whatever arrangements they may suggest, the status and efficacy of the examination will still depend chiefly

What Jacques Maritain has said of the educationist is true also to some extent for the doctor: "What is of most importance to the educator is a respect for the soul as well as the body of the child, the sense of his inmost essence and internal resources, and a sort of sacred and loving attention to his mysterious identity, which is a hidden thing no technique can reach."[2] Doctors who have learnt to look at patients in this way are able to testify how much this aspect of the matter has counted for in their dealings with them.

Because of this, the Christian doctor believes that he is within his rights when he insists that moral issues must be faced. There is a Christian attitude to life and death which it is necessary to have clear and to come to terms with if familiar issues confronting the doctor in relation to the use of contraceptives, abortion, and artificial insemination, venereal-disease control, euthanasia, sterilisation, and prefrontal leucotomy, as well as more remote questions like human experiment and b experiments, are to be responsibly dealt with. Christian has an attitude to health which makes hi it in more complicated terms than that of 100% globin and saturation with vitamin C and which e him to appreciate the value of people who may b from healthy by normal medical standards political, moral, and social context in which the d operates cannot be lightly taken for granted, as were of no account; for it influences the doc decisions and procedure on innumerable points. education of the doctor is not a matter of indiffe Its narrow specialisation and its system of cra may itself have been largely instrumental in m the rise of the doctor-technician inevitable rather any attempt on the part of members of the prof to reason out the matter. These are issues which to be taken seriously by every doctor concerned the efficient discharge of his professional duties, though he will not always agree with our point of in relation to them.

Special Articles

THE MEMBERSHIP EXAMINATION

FUNCTIONS AND CONDUCT

IN comitia last week the Royal College of Physicians of London accepted the following report from a committee[1] appointed last year "to consider whether the examination for the M.R.C.P. as regulated and conducted in the past can meet the needs of the future, and to make recommendations."

The Committee's Report

Since the war the membership examination has been variously criticised by fellows, members, and candidates. In reviewing its functions and conduct the committee have kept in mind especially the following opinions:

1. That neither this examination nor any other suffices to test competence as a physician.
2. That the need to obtain membership overshadows the years after qualification and stops young men from making investigations, or gaining experience abroad, which would profit them more.
3. That success or failure in this examination is governed too much by chance; compared with those of other examinations, its results are less predictable.
4. That it imposes undue strain on candidates, on examiners, and on hospitals.

FUNCTIONS OF THE EXAMINATION

The committee agree that recognition as a trained specialist should not depend wholly on the result of an examination; indeed, more emphasis should rest on training received and on work well done. Ability to pass examinations does not imply corresponding ability to practise medicine, and people who concentrate on the technique of satisfying the examiners are liable to miss their best opportunities of education. At the same time, the decision whether a man is to advance in the profession should not be left entirely to his own teachers, whose estimate of capacity can never be unaffected by personal likes or dislikes. The committee therefore believe that in the selection of future physicians there is still need of an examination, conducted outside the medical schools, at which all comers may prove their worth.

At what stage of training should this be taken?

Many of the criticisms of the present examination, and some of its shortcomings, arise from difference of opinion about its purpose. On the one hand, membership o college is widely regarded as the hallmark of the spec and the examination is looked on as a final test; in case it should presumably be taken at the end of five years' postgraduate training now accepted as minimum preparation for specialist status. On the o hand, teaching hospitals more and more de membership as a qualification for the post of re or chief assistant; and candidates are thus encourage take it early. No examination can fulfil two such diffe functions, and a choice must be made between them

Postponement until five years after qualification w have several serious drawbacks. The prospect of examination so long ahead would hinder develop along lines of personal aptitude or interest, and for t who want to specialise it would mean interference their chosen career. This objection could be partly by letting the candidate take the examination i specialty, such as dermatology or psychiatry; but committee do not favour this big change. They t it better that the examination should generally pre specialisation.

In the committee's opinion, membership of the co should signify a knowledge of general medicine justifies further training as a consultant, and the exam tion should therefore be a test in general medicine. a level higher than that required for qualification. should be taken early in training, normally about t years after qualification, when most candidates will ha completed their term as junior registrar.

CONDITIONS OF ENTRY

The committee see no need to alter By-law C. which states that candidates must be at least 23 y of age; but they recommend that no candidate sh be admitted to the examination until he has been quali for eighteen months.

They carefully considered whether the college sh require the candidate to have held house-appointm for a given period, and whether he should pro evidence of hospital work performed to the satisfac of his chiefs. Clearly, if the examination is taken years after qualification, the successful candidate have to prove himself by his work during several y further training; and there is therefore less reason he should do so before he becomes a member. Aga this is the fact that many of those attaining the mem ship turn at once to specialties, such as psychia and, unless the college insists on their having ho experience of general medicine before the examinat some members may become specialists without ha had it at all.

---

[1] The members of the committee were LORD MORAN (president), Dr. GEORGE GRAHAM, Dr. WILLIAM JOHNSON (d. March 15), Dr. DONALD HUNTER, SIR LIONEL Prof. A. W. M. ELLIS, Dr. DONALD HUNTER, Prof. A. J. LEWIS, Prof. W. G. WHITBY, Prof. E. J. WAYNE, Prof. R. V. CHRISTIE, Dr. F. AVERY JONES, Prof. BARNARD, Prof. R. V. CHRISTIE, Dr. T. F. FOX, and Dr. H. E. A. BOLDERO, J. McMICHAEL, Dr. T. F. FOX, and Dr. H. E. A. BOLDERO, (registrar).

eless, the committee would admit that no ordinary e can feel wholly confident so long as he thinks examiners are entitled to condemn him for econdite information. A clear definition of the purpose of the membership examination should be helpful. The committee believe, indeed. art from reducing the frequency of entry—the an do most to relieve the strain on candidates by that they are always examined in general . The presence of a colleague throughout all vs should restrain any tendency for examiners ler too far into their own fields, and should much to suppress hopes or fears founded on the n of chance.

miners

ree that the burden on the examiners must be d, and the committee recommend that the of the clinical examination should be reduced days—or four at most. If, as proposed above. e spent with each candidate is lengthened from o forty minutes, and the examiners examine in e number of examiners needed will be consider- ger. Hitherto the Censors' Board have sought ors only among fellows who have previously s censors; but if the committee's recommenda- pproved, the number of former censors available longer suffice. Under the by-laws of the college, censors bear entire responsibility for the results examination and they should therefore continue uct, alone, the final viva. The committee advise, r, that the censors should in future be assisted by ers appointed by the comitia on the nomination council. These examiners need not have served ors, and should, in fact, be younger than most rs of the Censors' Board.

spitals

al examination on the recent scale have likewise he endurance of the London teaching hospitals. ave had to provide suitable patients and accom- the candidates in the wards. Heavy work falls registrars responsible for the local arrangements. e committee think that the honoraria payable se services to the college might properly be dered.

s been usual, and remains desirable, for the clinical ation to be held in hospitals where one of the ers is on the staff. The appointment of a larger of examiners should mean a larger choice of ls fulfilling this condition.

her possible means of taking the load off the ls would be to transfer the clinical examination examination hall at Queen Square. Having red this solution in some detail, the committee nvinced that it would injure the character of the ation and would create formidable difficulties tice. They hope that it need never be attempted. committee recommend that in the clinical exami- some of the candidates should, if convenient, be ed at regional board hospitals in the London area. e present, at least, they do not think it necessary isable that the examination should be carried to cial centres.

PUBLISHED WORK

committee agree that membership of the college be kept open to candidates of special accomplish- who can suitably be excused the ordinary examina- They do not, however, recommend any change in levant regulation which requires submission of ed work to the Censors' Board.

CONCLUSIONS

committee's main conclusions can be recapitulated ows.

1. Membership of the college should signify a knowledge of general medicine that justifies further training as a consultant. The examination should, therefore be a test in general medicine, on a level higher than that required for qualification.
2. The examination should be taken early in training, normally about two years after qualification.
3. No candidate should be admitted to the examination until he has been qualified for eighteen months.
4. On entry, candidates should be asked to give details of the appointments they have held, and also to nominate a referee who (on request) could say exactly what work these appointments have involved.
5. Throughout the clinical examination, examiners should examine in pairs.
6. The candidate should have forty minutes in which to examine his long case and should be questioned on it for twenty minutes, a short case being used in addition if the long one proves inadequate. Twenty minutes should be allotted to the short cases, which should be two or three in number, and during this time the candidate will be accompanied and questioned by the examiners. The maximum marks for the long case and for the short cases should be 70 and 50 respectively.
7. In the pathological viva candidates should no longer be asked to identify histological specimens, and little importance should be attached to diagnosis from preserved pathological specimens. The two examiners should sit together.
8. The final viva should be used only for reviewing the merits of candidates who have not yet fully satisfied the examiners.
9. Save in exceptional circumstances, candidates should not be allowed to sit the examination more than twice in twelve months.
10. The duration of the clinical examination should be reduced to three days—or at most four.
11. The censors should in future be assisted by examiners appointed by the comitia on the nomination of the council. These examiners need not have served as censors, and should in fact be younger than most members of the Censors' Board.
12. In the clinical examination, some of the candidates should, if convenient, be examined at non-teaching hospitals in the London area.

The committee recognise that their proposals are for functional rather than structural change; but they believe that the total effect of these proposals, and especially of numbers 1, 5, and 9, would be to remedy the defects, or remove the grievances, to which their attention has been drawn. If, after a trial period, further action is seen to be necessary, it should be taken. The committee's final recommendation therefore is that within two years the membership examination should again be reviewed.

INTERNATIONAL CONGRESS OF OTOLARYNGOLOGY

SESSIONS IN OXFORD, CAMBRIDGE, AND EDINBURGH

AFTER the main business of the congress, in London from July 18 to 23, members were offered a choice of visits to three other centres, where meetings were held on Monday and Tuesday, the 25th and 26th.

OXFORD

The large number of members who visited Oxford were warmly welcomed, and here, as in London, the arrangements made for their accommodation and entertainment were distinguished by efficiency and forethought. The reception by the British Council at Magdalen, the tours of the colleges, and the motor-coach trips to the Shakespeare Memorial Theatre at Stratford were well attended.

The academic programme opened with a discussion on *Intracranial Infections* in the Taylorian Institute on Monday morning, with Mr. R. G. Macbeth in the chair.

Sir HUGH CAIRNS emphasised the importance of the subdural space and pointed out what scanty attention on the examiners. Even working under present conditions, the ideal examiner can make full allowance for the fact that one candidate has merely had to collect supporting evidence for a diagnosis apparent from the door, whereas another has been faced with an uncoöperative, deaf, or aphasic patient whose condition required days or weeks of hospital study before it was elucidated. The ideal examiner discounts spot diagnosis, rates the catalogue mind at its true worth, sees no disproportionate significance in ignorance of his own specialty, and is not antagonised by doctrine that he does not accept. But under present conditions, even the ideal examiner must sometimes be fatigued, and something less than ideal; and it ought to be impossible for any candidate to attribute his rejection to the prejudice, antipathy, or impatience of one examiner questioning him alone. The committee therefore recommend that examiners should *examine in pairs throughout the clinical examination.*

The time allowed for questioning should be long enough to obviate any impression of hurry, and the committee recommend that it should be extended by ten minutes. The candidate should have forty minutes in which to examine his long case and should be questioned on it for twenty minutes, a short case being used in addition if the long one proves inadequate. Twenty minutes should be allotted to the short cases, which should be two or three in number, and during this time the candidate will be accompanied and questioned by the examiners. The maximum marks for the long case and for the short cases should be 70 and 50 respectively. The examination should be so organised that the time needed by examiners for discussing the candidate's merits will not be deducted from the time allowed for questioning.

Pathological Viva

An examination in pathology should be conducted by pathologists. The committee wish it to be clear that the membership viva, conducted by physicians, is intended not so much to test the candidate's knowledge of pathology as to ascertain whether he can apply that knowledge to clinical medicine. At present he spends ten minutes in examining histological slides, after which two examiners, sitting separately, question him for ten minutes each: they confront him with pathological specimens, X-ray photographs, electrocardiograms, or laboratory reports, which serve as subjects of discussion. The committee recommend that candidates should no longer be asked to identify histological preparations, and little importance should be attached to diagnosis from preserved pathological specimens. The two examiners should sit together.

Final Viva

The committee debated whether the final viva should be abolished. They favour its retention, but hold that it should be used only for reviewing the merits of candidates who have not yet fully satisfied the examiners.

NUMBER OF CANDIDATES

Last July there were 596 candidates, compared with 161 in July, 1938. In the past year the entries have declined; but they remain—and unless action is taken, are likely to remain—at a level that makes it hard to arrange and conduct a satisfactory clinical examination. Believing that the numbers should be substantially reduced, the committee considered means to this end.

A primary examination, taken a year or two before the final, would eliminate some of the less promising candidates; but the committee had already rejected this proposal on other grounds. Alternatively, it would be possible to use part of the membership examination as a sieve through which the candidate must pass before admission to the clinical. The committee discussed in particular a suggestion that any candidate unsuccessful in the written papers (or in the written papers plus the pathology viva) should be told to proceed no fu which would save everybody time and trouble, the disadvantages of this arrangement seem to ou the advantages. First, it would alter the presen ception of the written and clinical examinati a single whole, in which outstanding clinical accon ment may compensate for weakness in the Secondly, the educational value of the clinical ex tion is far from negligible, and candidates excluded fairly complain of not having a run for their Thirdly, separation of the written papers fro clinical, and their use as a qualifying test, migh them undue prominence in people's minds an encourage candidates to concentrate on book learn

The committee concluded that the over-strain machinery of the examination should be relie possible without altering its essential structure, an *think that the numbers can be made manageal* simply lengthening the intervals at which cand may present themselves. The present custom by many attempt the examination once every three m has been reasonably criticised on the ground th short intervening period of preparation is unlik have made a man an appreciably better doctor; it has accordingly been argued that nobody should on two successive occasions. The committee feel tha a rule might bear hardly on individuals with little t their disposal, and especially on entrants from abroa cannot stay long in this country. They therefore the proposal made by the Standing Committ Members, and recommend that, save in excep circumstances, candidates should not be allowed the examination more than twice in twelve m The probable effect of this change can be gauged the fact that in July, 1947, 156 out of 554 cand were entering for the third or fourth time within t months, while in July, 1948, the figure was 21 of 596.

STRAINS

The Candidates

The committee were told that the examination is of an ordeal than formerly. Candidates approach it an anxiety that sometimes lowers the quality of hospital work. This state of mind infects others, an current attitude towards the membership has be morbid rather than natural. The mental stra enhanced (it was suggested) by continuation o examination over several weeks, during which candidate must three times steel himself against news.

In so far as excessive strain exists, it will be ge deplored. But the examination itself is much what i before the war, when it aroused less dread. Admit the large number of entrants has produced a pr and sometimes perhaps a haste, that allows unsucc candidates to suppose themselves inaccurately sort the machine; but the major causes of emotional te must be sought in the circumstances of the time. coming of the National Health Service, and espe its terms of remuneration in different branches of pra have generally strengthened the motives for securin membership, as a step to consultant status. Ma the older candidates, having spent years in the Ser must gain their objective quickly; only by keeping training grants and securing higher appointments they hope to follow their chosen career and at the time perhaps support a wife and children.

The need to refuse no chance explains why so men, both senior and junior, have been presenting t selves every three months—an enterprise that mus all but the most phlegmatic. It explains why so "have a go" when they know themselves ill-prep and knowledge of incapacity is no doubt a con reason for nervousness in this as in other examina

be a large receptor surface exposed to an air
t which varies in velocity from one part to
r.

Tuesday, in the department of anatomy, a demon-
n of ancient anatomical books, anatomical speci-
and radiographs of interest to the otolaryngologist
ranged by Prof. H. A. **Harris** and Dr. **Michael**
r. An instructive series of slides illustrated the
mount of elastic tissue in the ligaments attached
stapedius muscle.

f. J. S. **Mitchell**, speaking on *Some Developments*
diotherapy, explained that the aim of clinical and
tory research in his department of radiothera-
s is to improve the treatment of cancer and allied
es. The two main lines of approach are: (1) the
ation to radiotherapy of the penetrating high
X radiation generated by the 30 meV synchro-
and (2) the combined use of radiotherapy and
therapeutic agents. Much further experimental
is necessary before the 30 meV synchrotron can
ed in treatment. Clinical trials of large doses
trasodium 2-methyl-1 : 4-naphthohydroquinone
sphate ('Synkavit'), mainly in conjunction with
tive X-ray therapy, have been carried out in 240
its with various types of advanced malignant
ur. The compound is of low toxicity and is
administered by repeated daily intravenous injec-
; it was given by intramuscular injection in 130
and intravenously in 110 cases. Large intravenous
produce almost immediate focal pain in the region
e tumour in some cases, especially where there is
involvement. The compound produces a small
useful improvement in the palliative results of
therapy in some cases of advanced cancer, and
all increase in survival time in cases of inoperable
ioma of the bronchus. Professor Mitchell presented
logical evidence, including ultraviolet photomicro-
nic studies, showing retrogression and degeneration of
ur cells attributable to the effects of the compound
in certain cases of adenocarcinoma, in addition
monstrating the improved palliative effects of the
ination of the compound and X rays.

EDINBURGH

Monday a discussion was held in conjunction with
Scottish Otological and Laryngological Society on
nous Thrombophlebitis and its Complications, in
Department of Surgery, with Dr. G. **Ewart Martin**,
dent of the Scottish society, in the chair.

fortunately, owing to illness, Prof. **Norman** M.
t, who was to have led the discussion, could not
ar, so the opening paper was delivered by Dr. **Berger**
mas. Dr. Thomas dealt with the complications of
mbophlebitis which might be met with in cases
biting a resistant strain of organism. He described
aseptic thrombosis of the lateral sinus, which may
uce a subacute external hydrocephalus (postotitic
ocephalus of Symonds) by back-pressure following
mbosis of the arachnoid granulations. This is seen
ventriculograms which show diffuse subarachnoid
out no shift of the ventricular system. Treatment
loyed consists of intravenous hypertonic saline
tion and control of the cerebrospinal-fluid pressure
a lumbar tapping. Where no improvement occurs
btemporal decompression is advocated with a simple
ate opening in the dura. Aseptic thrombosis of the
bral venous branches of the lateral sinus is often
t in onset, the patient first complaining of loss of
on, or of seizures due to cerebral damage following
mbosis of the veins. Ventriculograms show localised
bral involvement with ventricular shift and displace-
t of the third ventricle. In these cases antibiotics
given as a routine, and the cerebrospinal pressure
ontrolled as before, using a ventricular tapping. A bone-flap decompression may be required. Turning to the septic complications of thrombophlebitis of the lateral sinus, Dr. Thomas referred to Gradenigo's syndrome, which he thought was less commonly seen since the introduction of antibiotics, and which he regarded not as an apical petrositis from direct spread but as a thrombophlebitis of the petrosal sinus. He recommended approach by elevating middle fossa dura. On the other hand, subdural empyema is more common in the present antibiotic era, especially after frontal sinusitis. Leptomeningitis, chronic serous meningitis, or pseudo-tumour cerebri is a basal meningitis where the blockage results in an extensive internal hydrocephalus requiring treatment by an approach between the tonsils of the cerebellum to the fourth ventricle. Dr. Thomas then spoke of cerebral and cerebellar abscess, now considered due to a thrombophlebitic process rather than to a direct spread. He showed that tension within the abscess interferes with the penetration of penicillin, but when the abscess is drained surgically, relieving the tension, penicillin can then be recovered from samples of pus from the abscess cavity.

Dr. A. **Brownlie Smith** contrasted his personal experiences of lateral sinus thrombosis in the pre-antibiotic and antibiotic eras. He felt that while diagnosis was often easy before the introduction of penicillin, many cases presented extreme difficulty, and complications were frequent. Since penicillin has been obtainable, the difficulty of diagnosis has increased, but the serious consequences of thrombosis have diminished. He described a case to illustrate the difficulty of diagnosis in the pre-antibiotic period. A child was apparently making a satisfactory recovery after paracentesis for an acute otitis media when the temperature suddenly rose to 103°F and the child looked ill. Immediate operation was decided on, and on exploration of the sinus, which appeared healthy, free bleeding was obtained. The ends of the sinus were packed off, and a piece of the vessel wall was removed. This showed the presence of a mural clot, and Dr. Smith showed several slides of the thrombus adhering to the wall. Some days later the child's temperature again rose and the jugular vein was tied, after which there was an uninterrupted recovery. Dr. Smith emphasised that the sole indication for interference surgically was the rise of temperature. Referring to his personal series of 29 cases of lateral sinus thrombophlebitis, Dr. Smith said that 22 were pre-antibiotic cases and 14 of these were complications of acute otitis media. There were 7 deaths (32%) in the 22 cases—1 from the anæsthetic, and 6 from undue delay in operating, either because the case was referred too late, or because the condition was not suspected until some days had elapsed in hospital. Of the 7 cases since the introduction of antibiotics, all were associated with chronic otitis media, and 5 were in children under the age of eleven years. No deaths occurred in these 7 cases, and in no case of the antibiotic period has the jugular vein been ligated. Dr. Smith said that either lateral sinus thrombosis is disappearing as a complication of acute otitis media, or, if it arises, it responds to antibiotic treatment and remains undiagnosed. The cardinal features of rigors, positive blood-cultures, and raised C.S.F. pressure with a positive Queckenstedt test are not now seen, and one is dependent on the temperature chart as the only certain guide to the possibility of thrombophlebitis. An unexplained fever in the face of penicillin treatment for acute otitis media is, in Dr. Smith's opinion, an indication for urgent operation. Lastly, Dr. Smith wondered if the anticoagulants might have a place in the treatment of thrombophlebitis thus suspected, though if they were successful the diagnosis could never be established. He had no personal experience of their use.

it had received at the hands of otological writers in the past. It was liable to infection as a result of osteomyelitis of the skull, particularly of the frontal bones after operations on the frontal sinuses. Such pachymeningitis was generally due to invasion by anaerobic streptococci or *Strep. viridans*. Staphylococcal osteomyelitis did occur, as a result of staphylococcal pyæmia, but it was very unusual to find a staphylococcal pachymeningitis. *Strep. viridans* seemed to possess some peculiar property which encouraged it to invade the subdural space. He emphasised the value of systemic penicillin in the treatment of this condition. Before this therapy was available the death-rate in 19 patients was 100%. Since using penicillin he had saved 5 cases out of 13. Massive removal of large areas of the frontal bone was no longer necessary in acute osteomyelitis; small patches of non-viable bone might still have to be excised after penicillin therapy. He demonstrated the X-ray appearance of subdural abscesses after they had been injected with 'Thorotrast,' and detailed their treatment by the insertion of a catheter through a burr-hole in the skull. Penicillin solution was then pumped through the catheter. He stressed the importance of keeping a very close watch for several weeks on the patient's progress after the cessation of antibiotic therapy. Infection might recur in the bone, the subdural abscess might loculate, or a brain abscess might develop. He made a plea for the planned approach to any intracranial infection. A careful clinical study, assisted by X-ray examination, should be supplemented by a determination both of the bacteriology and of the sensitivity of the bacteria to various antibiotics. Then, particularly when the disease was the result of infection by *Ps. pyocyanea* or other gram-negative bacteria, a massive short course of streptomycin should be given. He deprecated premature exhibition of antibiotics until the results of the bacterial study were to hand, since so many of the invading bacteria were prone to become resistant to treatment.

His words recalled a phrase of Wilfred Trotter's: "It is particularly necessary, therefore, for those who possess the admirable temperament of the surgeon, to guard against allowing themselves to mistake mere senseless activity for true surgical determination and promptitude."

Mr. J. B. PENNYBACKER described the modern treatment of brain abscess. He outlined the neurological surgeon's approach to the disease—i.e., the deliberate delay until the abscess had been surrounded by a thick capsule and then the excision of the abscess as though it were a tumour. He deprecated any approach to an abscess in the temporosphenoidal or cerebellar lobes through the infected mastoid cavity, and dwelt on the superior results obtained by tapping the abscess through a separate burr-hole in the skull. The most diagnostically significant signs in a temporosphenoidal abscess were aphasia and a quadrantic homonymous hemianopia in the upper part of the visual field. The cerebellar abscess caused fairly obvious symptoms and signs—loss of tone and of muscular balance on the homolateral side of the body, and nystagmus. He showed that brain abscess was still a grave disease by quoting the case-mortality rates, 44% for cerebellar, 32% for temporosphenoidal, and 20% for frontal abscesses. These figures represented a mass of clinical material, some of which had been under treatment before the introduction of antibiotics, and therefore one could look forward to considerable improvement in the future.

Mr. J. B. CURTIS described the technique of percutaneous angiography, and showed several X-ray plates of the resulting appearances in health and in brain abscess. In his view this method of investigation was safer than ventriculography, but owing to a zone of œdema around the abscess it was impossible to demonstrate sharply the edge of the abscess. He used diodone in performing the arteriogram, and had not s death resulting from this drug. It should not be patients who were prone to asthma or other va allergic complaints.

On the second day Prof. W. E. LE GROS CLARK on *Neurological Studies of the Olfactory Systems*, illu his remarks with some admirable diagrams. One ga that the olfactory cortex, under the close examina the modern anatomist, had been found to be les sive than was formerly thought. He dwelt on the importance of the anterior commissure as a path olfactory stimuli.

Dr. GRAHAM WEDDELL then spoke on some o tions on the *Innervation of the Epiglottis*. He demons that the posterior or laryngeal surface of the ep was covered with numerous large nerve-endings, con with a very rich network of nerve-fibres. He su that these nerve-endings played a part in the respi reflex, and he described a physiological expe which appeared to support this hypothesis.

Mr. M. A. ALLISON, whose paper was read by Pr Le Gros Clark, demonstrated by means of slides changes produced by partial or total ablation of olfactory bulbs.

CAMBRIDGE

The programme in Cambridge was arranged so the delegates, who had had a very hot and busy w London, might find some relaxation in combining work with visits to many of the old and more be buildings of the colleges and university. The w though exhausting, showed Cambridge at its best, the coolness of its cloisters and ancient interiors delightful contrast to the blazing sun outside.

The Vice-Chancellor gave a reception in the Schools on Monday evening, and his guests could at will through its historic rooms. In the morning Dean of Ely had welcomed the associate members to lovely garden and showed them round the Cath and in the afternoon the delegates, after visiting of the colleges, returned to tea in Caius College Tuesday afternoon the Regius Professor of Pl and Lady Whitby held a garden party in Dow College, which made a delightful ending to the Camb visit.

The scientific side opened with a short acco the *History of the University Medical School* by Sir Li WHITBY.

This was followed by a stimulating paper by Prof E ADRIAN on his recent work on the *Analysis of S by the Mammalian Olfactory Organ*. He explained the sense of smell has been investigated by recording discharge of nerve impulses in the fibres of the olf bulb and tract. The olfactory epithelium can stimulated mechanically or by osmotic and disturbances, but the normal stimulus is the move over it of a current of air containing odorous molec The intensity of excitation depends on the concent of the substance and the rate of air flow, but the rel importance of these two factors varies with diff substances, owing probably to differences in the of removal from the receptor endings. Since the current is faster in the more accessible and slower in more remote parts of the olfactory organ, the distri and time relations of the excitation over the whole vary with the nature of the stimulating mat Although there is some indication of differential sensit in the receptors, the discrimination of smells pro rests mainly on differences in the general patte excitation during each inspiration. As with sights sounds, therefore, the discrimination of smells is possible by the elaborate structure of the sense rather than by the variety of the receptors in it. the olfactory organ the essential requirement is that

Letters to the Editor

EXPERIMENTS ON ANIMALS

—What amount of suffering is it legitimate to
in the course of experiments on animals? The
n has *arisen from a study of some papers*
ed in recent years and describing Canadian and
an experiments calculated to inflict the maximum
ry consistent with the temporary survival of the
s, which are then studied physiologically. A
machine has been designed in which unanæsthetised
ith paws bound together, are dropped 40 times
nute. In one experiment 10 rats were subjected
falls in $17^1/_2$ minutes and died on the average
utes *later; another 10 subjected to 800 falls in*
utes died on the average in 47 minutes. The
s were not unconscious. In another experiment
gs, temporarily anæsthetised, had their thigh
s contused by 700 to 1000 blows with a light raw-
allet on each leg. The anæsthetic was then at
iscontinued; 25 of the dogs died after intervals
g from 50 minutes to about 9 hours. References to
apers describing these and other exceptionally
l procedures will be given to responsible inquirers
uest.

should be the last to underrate the importance of
ments on animals: but that importance does not
de all other considerations. There must be a
to the doctrine that the end justifies the means.
912 report of the Royal Commission on Vivisection
whose 7 signatories were eminent medical men,
mended the principle that is now embodied in the
rule attached to British vivisection licences: "If
imal at any time is found to be suffering severe pain
is likely to endure, such animal shall forthwith
ainlessly killed." This rule applies even when
ain object of the experiment has not been attained.

therefore invite scientists to assert with us that
nents of the kind to which we have referred at the
ning of this letter are to be condemned as shocking
normal human conscience. We suggest that in
ing his procedure every experimenter should
stly consider whether the infliction of the pain
ved is really justifiable in the interests of medicine
ience, and try to devise techniques that will reduce
ing to a minimum.

JOHN R. BAKER
F. C. BARTLETT
A. C. HARDY
E. HINDLE
C. W. HUME
W. R. WOOLDRIDGE.

R,—Despite the attacks of antivivisectionists, the
sity for animal experimentation for the relief of
n suffering is more and more generally accepted.
public realises that laboratory experiments per-
ed under licence in this country, after their desira-
, has been justified to the satisfaction of the
inted medical authorities, are invariably conducted
humanity.

is because of the trust that has thus been accorded
e general public that it is incumbent on the medical
ssion to refuse to condone, by silence, unjustifiable
tion of suffering on animals. A series of experi-
s have lately been recorded under the title of
t of Chronic Fear on the Gastric Secretion of HCl
ogs. I do not wish at this juncture to discuss the
tific validity of the experiments or the conclusions
n, but to call attention to the cruelty with which
were conducted.

ven dogs were used—as a preliminary they were operated
render them incapable of barking. The animals were
in metal screen cages, and, in the words of the author, an attempt was made to induce and maintain a state of chronic fear in the animals by strong electric shocks administered to the animals through specially constructed grids making up the floor of the cages. Combined with this form of stimulation, was an electric buzzer which might act either with or independently of the shock. The stimulus was administered by a mechanical device permitting some randomisation of the intervals between the stimuli—74 stimulations being administered within each succeeding twelve-hour period. During the night the grids were often short-circuited by fæces; otherwise, the dogs were stimulated at irregular intervals night and day. The experimental period lasted six months. During this period an occasional break of a few days allowed control measurements of HCl secretion to be performed on the resting animal. Otherwise, the arrangements for arousing in the dogs a state of chronic fear and intermittent pain for a continuous period of six months seem to have been effective.

Science and humanity know no frontiers and no-one who knows the selfless devotion and humanity of our American colleagues would doubt that a more general knowledge of these experiments, at present hidden in a specialised periodical, would arouse widespread indignation. It would surely, in some degree, involve us all in the dishonour that such practices cast on medical research were we to ignore them for fear that attention drawn to them might furnish ammunition for unscrupulous arguments of antivivisectionists.

Newlands, Frenchay, near Bristol. F. GOLLA.

THE MENSTRUAL CYCLE

SIR,—The facts forming the basis for my belief that the suprarenal cortex plays an important part in the determination of sex are briefly as follows.

Whilst the constellation of chromosomes at fertilisation determines the genotypic sex of the zygote, an intermediate sex-determining mechanism has been evolved in vertebrates which gives anatomical and physiological expression to this genotype. That this intermediate mechanism is responsible not merely for sex differentiation but also for sex determination in any but the narrowest genetic sense is clear from the fact that the undifferentiated gonad is ambivalent—i.e., capable of developing into either testis or ovary. The elucidation by Lillie of the "freemartin" phenomenon and the experimental investigations of Danchakova, Wolff, and many others have demonstrated that the sex-steroids can influence gonadal development, even to the point of complete reversal of the genetic sex. It can, therefore, be assumed that these substances, in so far as they occur in the early embryo, will play an important part as intermediate inductors in the normal mechanism of sex determination. In human beings the only sources of sex-steroids before the differentiation of the gonads are the maternal plasma, the placenta, and the suprarenal gland of the embryo, which begins to differentiate at the 6 mm. stage, and shows a well-defined fœtal type of cortex at the 10 mm. stage—i.e., considerably in advance of the differentiation of the gonads. Abundant evidence suggests that the fœtal adrenal cortex is identical with the androgenic X-zone of the permanent cortex. These facts taken together with the close anatomical relation of the suprarenal gland to the developing gonad and the well-known association of adrenal abnormalities with intersexuality make it highly probable that the adrenal gland plays an important part in the normal mechanism of sex determination, and Professor Zuckerman's comment (July 23) that such a belief lacks scientific foundation is certainly not justified. Whilst the details of the mechanism are not yet understood, it may be assumed that part of the adrenal function is to counteract the effects of maternal and placental œstrogens.

In stressing the importance of suprarenal cortical hormones in determining the events of the normal menstrual cycle, I do not wish to supplant the hard-

In England Now

A Running Commentary by Peripatetic Correspondents

So the Jutes have invaded Kent again, and have penetrated as far as Richmond, the only serious opposition having been offered by St. Thomas's Hospital. But we had already invaded Copenhagen this summer, clean-shaven, it is true, and by steamer as befits modern dermatologists. The steamer was the *Kronprinz Frederik*, and austerity ceased from the moment we stepped on her comfortable decks. From Esbjerg to Copenhagen one crosses three islands linked by bridge and train ferry. Danish farming unrolled itself before our eyes, and having heard so much of its advanced perfection we were pleased and surprised to see so much of it done by horses. But Denmark is short of petrol and diesel oil.

Copenhagen is a charming, leisurely city; no hurry, no bustle, and in consequence, as one of the party observed, no rosacea. Architecturally it suggests that the Age of Reason so far forgot itself as to have an affair with the Russian Ballet. Sober dignified 18th century façades have their silvery elegance mocked by a bulbous dome or a twisted sugar-candy spire in gleaming gilt. Hans Andersen's little mermaid in bronze watches it all from her sea-wet rock. Unlike the Spartans', her tidy wet hair needs no combing.

Our first visit was to the famous Finsen Institute and its hospitable director, Prof. Svend Lomholt. We saw with envious eyes the superb light-therapy installations in action, and were then given an admirable display of cases, which included some Continental rarities not often seen in this country, such as acrodermatitis chronica atrophicans. Professor Lomholt was enthusiastic over his results with calciferol in lupus. The patients themselves were an interesting study, and the doctor-patient relationship seems to be as near perfect in Denmark as human nature can make it.

Another day was spent in the Rijkshospital with the genial Professor Haxthausen. An excellent clinical meeting was followed by a demonstration of simple practical therapeutic methods. Success in treating skin diseases is 50% a matter of detail, and the doctor who can stop a patient scratching will do far better than an expert on the latest antibiotics. Professor Haxthausen combines inspired common sense with scientific scholarship. One leaves his clinic filled with a happy zest at belonging to such a good profession, and a growing enthusiasm for the Anglo-Danish entente.

Life in Copenhagen is not all work. The Tivoli Gardens, in the middle of the city, have their restaurants and fun fair, with music and everyone managing to be happy without being raucous. A glass of Schnapps costs 2s. and adds to gaiety. If anyone is likely to ask you " Qu'as tu fait, toi, de ta jeunesse ? " I should advise spending a bit of it in Copenhagen. We lacked only one thing —a word. " Hospitality " in our country suggests Spam and a reconstituted egg. It has come down in the world since the Roast Beef of Old England days; and is now a poor little undersized creature. It is absurd to apply the same word to the feasts we were given in Denmark. Hospitality there is a noble animal, by Lucullus out of Gargantua. After three days of it we stepped on to our home-bound train like happy boa constrictors.

* * *

When my thrice-weekly morning help, a farmer's daughter, told me not long ago that she felt tired and slack because she had been eating a lot of lettuce and that it always had this effect on her, I murmured that lettuce was supposed to induce sleep. Her brother, she continued indignantly, had said it was imagination, though he himself had reported that the waitresses in the café he frequents on market days complained of heaviness and fatigue during the season of salad meals. I thrust away my vague feeling about the properties of lettuce, and suggested that lack of sufficient other nourishment with the salad might explain her feelings; but this was denied. In fact, eggs, milk, cheese, and occasional rabbits are quite plentiful in her home; so lettuce, which itself is hardly food, is generally well supported. The plump girls in the café, too, are no doubt fed liberally, for the establishment caters f hearty country inhabitants of our district and is u to muzzle the oxen—in other words, the wai I go in sometimes to buy the substantial fresh c sandwiches sold over the counter, and note that the served look more appetising and abundant than I have had at pretentious hotels.

Speculating on the nursery lore at the back mind which had made me say that lettuce m sleep, I wondered what my books had to say *Lactuca*. The *B.P.C.* has an extractum prepared from the expressed juice of *Lactuca* with a dose of gr. 5–15. " Lettuce," it says, " is sedative and hypnotic, and is used in irritable It also describes " lactucarium," or " lettuce hard lumps of the dried juice which are green whe and turn brown on keeping. The sedative su seems to be the colourless, tasteless, crystalline lac I turned to the botanists and found that Hooker[1] " The thickened juice of the cultivated lettuce, thridace, is used as a narcotic, and preferred to in cases where there is reason to fear the stu action of the latter." In Folkard's enchanting I read : " The old poets prescribed a bed of Let those who were unable to obtain repose; and states that Lettuces of all description were tho cause sleep. Pope, referring to its soporific q has said of the Lettuce :

> ' If your wish be rest,
> Lettuce and cowslip wine, probatum est.' "

Doubtless our grandmothers and theirs in turn recommended lettuce for sleep since the time of although the news has not yet reached the judging from the mutterings of a girl of that she brought me a plate of it, saying in her own la " Fancy eating grass." Therefore let all who colons to digest it and no allergy (a friend of " covered with hives " if she but taste it) eat lett supper and need not poppy nor mandragora.

The so-called dead languages are so very much in us that when we come across people from whom are totally absent the scales fall from our eyes crash. I do hope the nursing experience now m won't cut into the classics. I have recently had through masses of death-registrations, copied in " lish " from medical handwriting by an intelligent European clerk. One in particular comes out as A *sectorasis* or even as *Atrix sedoroni*, both of which good enough to start out as entities on their own. the palm goes (and what psychopathological vis not opened up ?) to the case of the elderly Indian departed this world on account of " Atheris secto cardic and penal failure."

* * *

The R.M.O. taking a class of students round the pointed with some pride to a girl who had been fully treated for pneumococcal meningitis. " But does she squint ? " objected a critical student. " E her and find the cause," replied the R.M.O. A few mo later the student, having examined the girl, repo " There is paralysis of the external rectus muscle the pupil is fixed." " What is the cause ? " asked R.M.O. " Nerve damage resulting from menin was the answer. The R.M.O. turned to the patient " the doctor your eye, Nelly," he said. The girl swift face-wiping movement and before the asto students had time to think, they saw in her outst palm—a glass eye.

* * *

Holidaying in the heart of Wilts I was not s my way in a small village and, not wishing to " I'm a stranger here myself," applied for directi a typical son of the soil wending his weary way a hoe over his shoulder. I was met with a sh the head and " No spik." " Parlez-vous franç I asked. " No spik." " Sprechen sie deutsch ? " spik." " Parlate italiano ? " " No spik." " Well, *do* you speak ? " " Ungarisch." I gave it up.

OSTRACISM OF THE TUBERCULOUS

—Many of us working in the field of tuberculosis he concern of Dr. Edelston (July 16) lest ostracism tuberculous should cause patients to conceal their and thus disseminate it. But one of his remarks, qualified, is in my view misleading and contrary eral experience. He writes "it is time that it was l that active cases of pulmonary tuberculosis can sed in general wards of general hospitals without aallest danger to nursing staff or to the non-ulous patients." Had he added "if adequate tions are taken" one might be inclined to agree. er, where cases of active pulmonary tuberculosis mitted sporadically to general wards it is unlikely mior nurses or even ward sisters are aware of what tions should be taken; nor are facilities for the ate disinfection and disposal of sputum and soiled usually available. Again, one wonders how often ulous patients in general wards are supplied with lual crockery, whether they are taught safe ing, and whether nurses tending them are urged r masks. My own feeling is that there is probably isk to staff in a well-run sanatorium than in eral hospital where positive-sputum cases are ntly admitted to the general wards.

r issue of July 16 also contained reports of papers by various distinguished authorities on tuberculosis rses and students. Dr. Marc Daniels, in his able ing-up, stated that it is now generally agreed that is a higher tuberculosis morbidity among hospital rs than in the general population, and drew atten-o the casual attitude towards tuberculous infection ny hospitals.

purpose in writing is not to exaggerate such risks ist, which in my view are almost negligible in ux-positive subjects where adequate precautions aken. I feel, however, that the proposal in Dr. ton's letter which I have criticised might, if acted lead to a perpetuation of the casual methods red by the above-mentioned authorities, which only tend to maintain a higher incidence of tuber-s disease in hospital workers.

dale Hospital, London, N.W.9. W. E. SNELL.

QUININE IN ACUTE MALARIA

,—The prevailing tendency amongst writers on the ment of malaria is to stress the virtues of the r plasmocidal drugs while showing remarkable erence to the established properties of quinine. attitude is also prevalent amongst newcomers to cal practice in the tropics—so much so that one is ed to conclude that the present-day teaching in cal medicine fails to stress the salient fact that ine is still our sheet anchor in the treatment of acute ria.

ose of us who through years of practice in the cs have learned to respect the unpredictable vagaries viciousness of malignant malaria in the non-ne, continue to regard quinine as the most reliable most effective of all the plasmocidal drugs in gaining ly control of an acute attack; and this still holds after giving fair trial to all the newer plasmocidal s. Furthermore, the prejudice expressed in some oritative quarters against the use of parenteral ine therapy—more especially against intramuscular tion—is wholly unjustified. With the patient rated by the persistent and intractable vomiting the profound toxæmia that so often accompany ks of acute malignant malaria, oral therapy is ly unreasonable; in such circumstances the nteral administration of quinine will not only save but will spare the patient hours—even days—of ess and suffering.

I consider that the basic procedure in the treatment of acute malaria in Africa consists in: (1) overwhelming the infection and so gaining rapid control of the attack with quinine either orally or, in special circumstances, parenterally (quinine acts promptly on the parasite in the early stages of schizogony): and (2) following through with a full course of one of the newer plasmocidal drugs. Dosage varies with the strain or species of the causal plasmodium.

Salisbury,
Southern Rhodesia. WILLIAM KERR BLACKIE.

SHOE LACES FOR THE STIFF-JOINTED

SIR,—Mr. Dundas Irvine's patients (July 30, p. 199) can give up their search for an instrument "to draw tight and tie shoe laces" if they use elastic shoe laces. These are supplied by the Soesi Co., 78, Upper Richmond Road, London, S.W.15, in various colours and sizes.

Birmingham. G. K. ROSE.

Parliament

QUESTION TIME

Grading of Venereologists

Sir ERNEST GRAHAM-LITTLE asked the Minister of Health if, in view of the fact that by reason of the downgrading of venereologists the total of accredited specialists would be reduced to a number wholly insufficient to deal with the increasingly anxious problem of venereal disease, he would review the position.—Mr. ANEURIN BEVAN replied: Boards are at present reviewing their medical establishments in the light of the needs of the service. It would not be proper for the grading of existing individuals to be influenced by considerations of staffing requirements.

Ambulance Services

Mr. BAKER WHITE asked the Minister what was the total strength of the ambulance services coming within the scope of the National Health Service in terms of personnel and vehicles; and what were the corresponding figures for public ambulance services on June 30, 1946.—Mr. BEVAN replied: The figures for the National Health Service (England and Wales) are whole-time drivers and attendants 7000 (approx.): ambulances 3321; sitting-case cars 824. The corresponding figures for public ambulance services before July, 1948, were obtained somewhat later than the date mentioned in the question. They are 4275; 3925 (including a large number of works and colliery ambulances still operating outside the National Health Service); and 366.

Hearing-aids

Mr. GERALD WILLIAMS asked the Minister what percentage of 'Medresco' hearing-aids have been found to be faulty.—Mr. ARTHUR BLENKINSOP replied: About 3% of the aids delivered to distribution centres are now returned as faulty. Of the aids issued to patients in the first year about 24% have come in for servicing or repair in England and Wales, but it is difficult to know how much of this represents original faults in the instruments. Mr. WILLIAMS: Has the Minister any idea how long it takes to repair these hearing-aids, because there is a great deal of complaint about this matter?—Mr. BLENKINSOP: Very often the repairs are minor servicing repairs. We regard the proportion of sets which come back for minor repairs and servicing as extremely small.

Spectacles, Dentures, and Wigs

Mr. WILLIAM TEELING asked the Minister how many pairs of glasses and how many sets of false teeth and how many wigs have been provided in the last 12 months; and how many demands are still outstanding.—Mr. BLENKINSOP replied: At a very rough estimate, about $4^1/_2$ million pairs of spectacles have been supplied under the supplementary eye service and between three and four million pairs are on order. No information is available as to the number of dentures. Up to May 20, 8000 wigs were ordered and 2600 supplied through the Ministry of Pensions, on the advice of specialists.

Birth-control Advice in the Colonies

Mr. R. W. SORENSEN asked the Secretary of State for the Colonies in which Colonies was appropriate birth-control gained and solid knowledge concerning the action of pituitary gonadotrophin and of the ovarian hormones. These account for the maturation of the follicle and corpus luteum, for the development of the endometrium, and for certain side-effects on secondary sexual characteristics. This leaves, however, a residuum of phenomena, especially in relation to the mechanism and timing of ovulation and menstruation and in connexion with collateral cyclic changes affecting the female organism as distinct from those which are confined to the sexual apparatus. These events which cannot satisfactorily be explained on a pituitary-ovarian basis are as constant and integral a part of the menstrual cycle as follicular and endometrial maturation. It is my contention that the scientific data available (including some which were provided by the work of Professor Zuckerman) allow the conclusion that these constant and important events of the normal menstrual cycle are largely determined by suprarenal activity.

TESTICULAR PAIN

SIR,—In his letter of July 2 Dr. Weale claims to defend "some fundamental tenets of orthodox surgery and physiology" but at the same time makes some unorthodox statements on anatomy. He asserts that the nerve-supply of the testis, its coverings, and the scrotum are all L 1–2. This is certainly not the view of the authors of our most orthodox textbooks of anatomy, who give the innervation of the testis as from the tenth thoracic segment of the spinal cord through the renal and aortic plexuses, of the superior part of the scrotum from the first lumbar segment via the ilio-inguinal nerve, and of the inferior and perineal parts from the (second) third and fourth sacral segments via the scrotal nerves and perineal branch of the posterior cutaneous nerve of the thigh. The genital branch of the genitofemoral nerve supplies the cremaster and a few filaments to the skin of the scrotum. The nerve-supply of the tunica vaginalis testis is not so clearly stated, but as it is developmentally a portion of the parietal peritoneum one may reasonably assume that its innervation is from the overlying somatic nerves.

The integrity of the genitofemoral nerve after operation in the case described could hardly be investigated by attempting to elicit the cremasteric reflex as suggested by Dr. Weale. It was clearly stated by Mr. Brown in his article that the coverings of the cord had been removed; therefore the cremaster muscle was no longer present after operation and no reflex could possibly have been elicited even in the unlikely event that the nerve itself had been preserved. The view that the loss of testicular sensation was due to damage to the ilio-inguinal nerve can also be ruled out since Mr. Brown informs me that he always identifies and preserves this nerve when operating on the inguinal canal, and furthermore that in this particular case there was no post-operative anæsthesia in the cutaneous distribution of the ilio-inguinal nerve.

The segmental innervation of the ureter is from the tenth to twelfth thoracic and first lumbar segments of the spinal cord, and this explains the descending nature of true visceral pain in calculus obstruction of the ureter as successive segments are involved. That irritation of the genitofemoral nerve can occur in this condition is known, since the cremaster is sometimes found to be contracted on the affected side with consequent retraction of the testis. If the motor fibres in the nerve can be thus involved it does not seem unreasonable to suppose that pain in the scrotum or even in the thigh is due to similar irritation of the sensory fibres in the nerve. At any rate the anatomical pathways are present for all three types of ureteral pain described.

Finally, one can perhaps understand the occu testicular pain in the cases of ruptured hydron and ruptured abdominal aortic aneurysm, but th ment that any retroperitoneal lesion can give testicular pain seems too sweeping. Carcinoma head of the pancreas, although retroperitoneal, d seem to be a likely or even possible cause of t pain. My views, however, are based mainly on ana grounds and I leave it to others with more experience to make their comments.

ATROPINE AND CURARE

SIR,—It is well known to pharmacologists that a and curare have similar actions, but the amo atropine required to produce neuromuscular blo large that it is not of much importance clinicall Sinha and I, working on the rat diaphragm found recently, however, that doses of atropine have a very small effect on the isolated diaphrag sensitise a preparation to curare, so that a dose previously was ineffective may increase the ac curare almost twofold. Doses of atropine and which separately are ineffective may together complete neuromuscular block.

As atropine and curare are commonly used cli this appears to be of some practical importance.

EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—On reading the letter from Dr. D. P. L (July 23), in which he mentions the verminous co of hedgehogs, I am reminded of an incident som ago. I found a fully grown hedgehog crossing road, captured it, and put it in a greenhouse w idea that it would help to keep down pests. lively when captured, but next day it was very le and I noticed that it had paralysis of the hindqu later in the day the paralysis had ascended to th quarters, and on the following day, when attemp feed it with milk from a pipette, it was obvio paralysis of the pharyngeal muscles had occurre animal was infested with ticks.

Shortly after this I happened to read an acc the *Journal of the American Medical Associatio* type of ascending paralysis occurring in some the United States which appeared to be due to a of tick fastening itself to the nape of the neck. removal of the tick allows the patient to recover. out suggesting that this can bear any relation to poliomyelitis it might suggest something to interested in the tick as a source of infection in the obscure diseases.

I am told by a friend interested in natural that if a hedgehog is found in the open in daylig almost always found to be sick, and will soon di own experience with captured hedgehogs confirm

Plymouth.
EDRIC WI

SIR,—On July 14 at about 6.30 P.M. a ho appeared on my lawn. It moved with difficul occasionally appeared to collapse on the nea leg as if there was some partial paralysis. Ot it seemed well and drank some milk. After a some half-hour it went into an adjacent cop reappeared on two subsequent evenings at th time (an unusual time for hedgehogs to be abou I was hoping to tame it; but after its third disappeared. I should say it was not fully Could it possibly have been suffering from poliom

ANCE BENEFITS DURING STAY IN HOSPITAL

R the provisional regulations operating since July 5, patient maintained free of charge in hospital has had ional Insurance sickness benefit reduced by 10*s.* a ut not below 5*s.*) after two months. If he has a nt who satisfies certain conditions, there has been her reduction; otherwise, benefit has been payable week after he has been in hospital for fourteen months. g on a report from the National Insurance Advisory tee, the Minister of National Insurance has made new ons to come into force on Sept. 5. In future, after two in hospital, the benefit of a patient with a dependant reduced by only 5*s.* a week, and there will be no further n if the beneficiary has arranged for all but 5*s.* of his to be paid to the dependant. Where a patient has no ants, his benefit will be reduced by 10*s.* a week after nths in hospital. After a year it will be reduced to t on discharge a resettlement sum will be available. he second year it will be finally reduced to 5*s.*

nts suffering from any form of respiratory tuberculosis able to receive 10*s.* (instead of 5*s.*) while they are pital, but the amount which is paid over to their ants, or which can be paid on discharge, will be ondingly reduced.

l College of Obstetricians and Gynæcologists

a meeting of the council held on July 23 Prof. Hilda was elected president in succession to Sir William tt. She will assume office in October. Mr. J. E. Stacey Ir. V. B. Green-Armytage were elected vice-presidents. ollowing officers were re-elected: treasurer, Mr. A. A. ell; hon. secretary, Mr. H. G. E. Arthure; librarian, W. Roques; curator of the museum, Mr. Aleck Bourne.

following were elected to the membership:

. Backus, Jessie E. C. Baird, T. E. C. Barns, Anusya Bhagat, Blakey, V. Y. Bockner, Sudhir Chandra Bose, M. B. Bruce, Cummin, Mona M. Davin-Power, R. G. Denniss, Henry man, Thomas Dougray, L. W. D. Drabble, C. T. F. Ealand, Emsley, G. M. Evans, J. J. Foley, P. S. Gardner, G. W. d, H. K. B. Geiser, Elizabeth Gilbertson, Marie P. S. Grant, Hammond, J. C. Harvey, John Henderson, J. A. Henderson, Hendry, R. W. Hutchinson, E. W. Ilangantileke, E. P. , F. G. E. King, J. M. King, E. W. Kirk, Joan E. M. Lambert, as Latto, J. G. Lawson, F. H. Leckie, E. M. Leyland, J. W. F. den, J. M. McCracken, Ian MacGillivray, H. N. Mansfield, Millar, Rustam Moolan-Feroze, L. O. Morgan, M. R. Neeley, R. Picton, J. G. Reynolds, N. A. Richards, Szulin Riterband, Roddie, J. H. Routledge, Choudhuri Abdus Samad, E. M. er, Olive C. Sandys, J. W. F. Scrimgeour, Sita Sen, J. G. n, Norah P. Sherlock, Appacuty Sinnatamby, J. A. McC. , Doreen M. J. Stracey, A. B. Swarbreck, J. L. Taylor, bhoo Datta Tewary, John Watson, G. F. J. Williams.

Royal College of Physicians of London

At a comitia of the college on July 28, with Lord Moran, the president, in the chair, the following fellows of the college were elected officers for the ensuing year:

Censors: Prof. J. Crighton Bramwell, Dr. J. Forest Smith, Prof. R. V. Christie, Dr. A. H. Douthwaite. *Treasurer:* Prof. W. G. Barnard. *Registrar:* Dr. H. E. A. Boldero. *Assistant registrar:* Dr. W. D. W. Brooks. *Library committee:* Dr. J. Bishop Harman, Dr. M. L. Rosenheim, Dr. R. R. Bomford, Lord Amulree. *Finance committee:* Dr. G. B. Mitchell-Heggs, Dr. C. T. Potter, Dr. F. Avery Jones.

The following were elected examiners:

Chemistry: Mr. Alexander Lawson, PH.D., Mr. A. E. Kellie, PH.D. *Physics:* Mr. Stanley Rowlands, PH.D., Mr. J. E. Roberts, PH.D. *Materia medica and pharmacology:* Prof. E. J. Wayne, Dr. E. F. Scowen, Dr. Bishop Harman, Dr. R. R. Bomford, Prof. A. C. Frazer, Dr. V. J. Woolley. *Physiology:* Prof. W. R. Spurrell, Prof. J. L. D'Silva. *Anatomy:* Prof. James Whillis. *Pathology:* Prof. R. J. Pulvertaft, Prof. W. D. Newcomb, Dr. Kenneth Robson, Dr. Arthur Willcox. *Medical anatomy and principles and practice of medicine:* Dr. K. Shirley Smith, Dr. C. B. Levick, Dr. E. R. Cullinan, Dr. T. C. Hunt, Dr. Robert Coope, Dr. H. L. Marriott, Sir Horace Evans, Dr. A. V. Neale, Dr. J. C. Hawksley, Dr. F. P. Lee Lander, Dr. William Brockbank, Dr. S. P. Meadows. *Midwifery and diseases peculiar to women:* Mr. D. H. Macleod, Mr. R. A. Brews, Mr. Arnold Walker, Mr. K. V. Bailey, Mr. Ian Jackson.

Public health: Part I, Prof. J. M. Mackintosh; *Part II,* Dr. J. Greenwood Wilson. *Tropical medicine: Section A,* Major-General Sir Alexander Biggam; *Section B,* Prof. George Macdonald, *Ophthalmic medicine and surgery:* Dr Dr. E. A. Blake Pritchard, Dr. Denis *medicine: Part I,* Dr. W. D. Nicol; *Part* Dr. Noel G. Harris. *Laryngology and ot* *Medical radiology:* Prof. Gilbert Stead, D.SC., Dr. Peter Kerley, Prof. D. Waldron Smithers. *Anæsthetics:* Dr. Robson, Dr. C. A. Keele, Dr. A. D. Marston, Dr. B. R. M. Johnson. *Child health:* Dr. Kenneth Tallerman, Prof. J. M. Smellie. *Physical medicine: Part I,* Dr. Jack Watson Litchfield, Prof. Sidney Russ, D.SC.; *Part II,* Dr. W. S. C. Copeman, Dr. D. C. Shields. *Industrial health: Part I,* Dr. J. A. Charles; *Part II,* Prof. R. E. Lane. *Murchison scholarship:* Dr. M. L. Rosenheim, Dr. J. F. Dow.

The following lecturers were appointed:

Sir Leonard Parsons, F.R.S. (Harveian Orator), Dr. E. R. Cullinan Parsons-Smith (Lu Dr. E. E. Pochin Prof. J. H. Dil Rolleston), Prof. E. C. Dodds, F.R.S. (Bertram Louis Abrahams), Lady Violet Bonham Carter (Lloyd Roberts)—all for 1950; and Dr. T. F. Fox (Croonian) for 1951.

The Baly medal was awarded to Sir Edward Mellanby for his services to physiology and his work on nutrition with particular reference to the accessory food factors.

The following having satisfied the censors' board were elected to the membership:

D. E. Aikenhead, M.D. Manitoba, C. D. Alergant, M.D. Lpool, Sivasithamparam Balasingam, M.D. Lond., Joseph Baragan, M.B. Cairo, E. M. M. Besterman, M.B. Camb., J. E. Blundell, M.B. Camb., R. E. Bowers, M.D. Lond., J. F. Britto, M.B. Bombay, D. E. St. J. Burrowes, M.B. Lond., L. J. Bussell, D.M. Oxfd, J. A. Chamberlin, M.B. Lond., Patricia Chippindale, M.B. Lond., E. S. Clarke, M.D. Chicago, M.B. Durh., H. R. Colquitt, M.B. Lond., Lorna Cooke, M.B. Lond., Christine E. Cooper, M.B. Camb., J. E. Cotes, B.M. Oxfd, C. J. Don, M.B. Lond., A. S. Douglas, M.B. Glasg., C. E. P. Downes, L.R.C.P., J. R. Edge, M.D. Leeds, R. H. Ellis, M.B. Camb., J. D. Everall, L.R.C.P., P. R. Fleming, M.B. Lond., R. V. Gibson, M.B. Camb., J. E. MacA. Glancy, M.D. N.U.I., J. M. Gooch, M.B. Melb., D. A. Gordon, M.B. N.Z., R. G. Gornall, M.D. Lpool, R. F. Griffith-Evans, M.B. Lond., L. N. Grunbaum, M.B. Camb., Stefan Grybowski, M.D. Polish Sch. Edin., R. O. F. Hardwick, M.B. West, M.D. Lond., Donald Whitfield, M.B. Camb., D. H. M. Woollam, Esme M. Wren, M.B. Lpool, E. A. Wright, M.B. Lond., R. J. Young, M.B. Belf., flight-lieutenant R.A.F.

Licences to practise and diplomas were conferred on those named in the reports of the Royal College of Surgeons below and in our issues of May 21, June 18, and July 23.

information and assistance made available to those desiring it; and in which Colonies was it forbidden.—Mr. D. R. REES-WILLIAMS replied: In none.

Foreign Workers

Mr. G. H. OLIVER asked the Minister of Labour whether he was aware of the low medical grade of many of the foreign workers admitted into this country and the resulting high rate of sickness among these workers; and whether, in view of the present difficulties in staffing and finding accommodation in our hospitals and sanatoria, he would seek authority to have all foreign labour adequately medically examined in *the country of origin before allowing their entry into this* country.—Mr. GEORGE ISAACS replied: Foreign workers recruited under official schemes for which I am responsible are already required to undergo a general medical examination, and an X-ray examination to detect tuberculosis, before they are accepted and brought to this country. In proportion to the numbers recruited, the cases of serious sickness have not been numerous, but as these workers are mostly displaced persons the privations which they have undergone may have resulted in some cases in breakdown in health after their arrival.

Public Health

Poliomyelitis

THE number of notifications in the week ended July 23 was poliomyelitis 96 (112), polioencephalitis 3 (5). Figures for the previous week are shown in parentheses. This is the second time since the seasonal rise definitely began in the week ended June 11 that the weekly notifications have been fewer than in the previous week. In 1947 the rise was remarkably steady once it had set in and the figure for the week ended July 19 (corresponding to the present week) was 193. This may portend a flattening of the curve of incidence. Multiple cases (poliomyelitis and polioencephalitis together) were reported from the following counties: London 7 (13), Berks 3 (2), Cumberland 2 (2), Devon 7 (9), Essex 4 (3), Gloucester 2 (6), Lancs 8 (7), Leicestershire 6 (2), Middlesex 11 (11), Northumberland 2 (0), Southampton 8 (14), Suffolk East 2 (0), Suffolk West 3 (1), Surrey 3 (4), Sussex East 2 (2), Yorkshire, West Riding 17 (19).

Film for the General Public.—In addition to the film for doctors, "Polio: Diagnosis and Management," mentioned in this column last week, a short film for the general public entitled "His Fighting Chance" will be shown in ordinary cinemas from Aug. 8 onwards. This deals with the modern technique of reablement after poliomyelitis, and the commentator is Mrs. Roosevelt. The running-time is 10 minutes. Copies will be obtainable from the Central Film Library, Imperial Institute, South Kensington, from about Sept. 1.

Births, Marriages, and Deaths

BIRTHS

BEYNON.—On July 27, in London, the wife of Dr. A. E. Beynon—a son.

GILMOUR.—On July 24, at Hayes, Middlesex, the wife of Dr. S. J. G. Gilmour—a son.

LOVETT.—On July 5, at Hargeisa, British Somaliland, the wife of Dr. W. C. D. Lovett—a son.

NAUTH-MISIR.—On July 25, at Romford, the wife of Dr. T. N. Nauth-Misir—a son.

SIMMONS.—On July 19, the wife of Dr. R. W. Simmons—a son.

MARRIAGES

BOWER—AITCHISON.—On July 26, in Birmingham, Brian Douglas Bower, M.B., to Pamela Mary Christine Aitchison, M.B.

LYLE—MAXWELL.—On July 23, at Peppard, Thomas Keith Lyle, C.B.E., M.D., to Jane Bouverie Maxwell.

MEIKLEJOHN—ASHFORTH.—On July 16, at Hayes, Middlesex, William Meiklejohn, M.B., to Audrey Jean Ashforth.

DEATHS

BARR.—On July 22, at Torquay, James Barr, M.B. Glasg., D.P.H., aged 81.

BREW.—On July 23, Richard William Brew, B.A., M.B. Dubl.

FEGAN.—On July 26, at Leverstock Green, Herts, John Herbert Crangle Fegan, M.R.C.S., aged 77.

JOHNSTON.—On July 26, in London, Loiza Elwell Johnston, M.R.C.S., aged 77.

O'NEILL.—On July 27, at North Cheam, Surrey, William O'Neill, M.B. N.U.I., aged 57.

ROSSER.—On July 25, Richard Picton Rosser, M.B. Edin.

WAGSTAFF.—On July 25, Charles Bertrand Wagstaff, M.R.C.S.

Notes and News

THE MATERNITY SERVICE

PRACTITIONERS will shortly receive from local e councils a statement, prepared by the Standing M and Midwifery Advisory Committee and endorsed Central Health Services Council, which speaks of standing about the nature of the medical services a for the expectant mother who is to be confined in home. There is, it says, a widespread belief among practitioners and the public that the agreement be doctor and a patient by which the doctor unde provide maternity medical services converts the what is commonly known as a "doctor's case" doctor accepts full responsibility for the antenatal the labour, and for the lying-in period. "This was not the intention: it was not intended in any way to the importance of either the antenatal clinics or the by the introduction of the maternity medical service the payment of a comprehensive fee, a general prac undertakes to examine the patient at the time of and at about the 36th week; to make a postnatal ex about 6 weeks after confinement; and to provide a tional medical attention if he considers it necessar response to a call from the midwife. *He is not* req undertake the more frequent routine antenatal su that is essential, nor to attend the labour, unless suc dance is considered necessary by himself or by the He may, of course, provide additional services if he so his remuneration being unaffected thereby. "The must undertake regular antenatal supervision even duplicates the examination of the general practitione the doctor makes it quite clear that he accepts full responsibility for the case during pregnancy, labo lying-in period. The general practitioner may of assume these full responsibilities if he considers it n But it is the hope of the Minister that, in domicilia wifery, the midwife will continue to be regarded as the attendant, supported by the antenatal clinic dur pregnancy, and working in coöperation with the practitioner who has had the opportunity to satisfy that there are no deviations from the normal in the general health during pregnancy nor obstetric compl towards the end of pregnancy and will come to he trouble arises during labour or the lying-in period. T wife will consider herself to be acting as a practising unless she has been informed to the contrary by the

REPEAT PRESCRIPTIONS UNDER N.H.S.

WHEN a doctor considers that his patient's treatmen *continue for longer than the first supply of* medicine and it is not necessary to see the patient again for sor if at all, the doctor may issue two or more prescript carbon copies of the same prescription bearing signatures) dated at suitable intervals. This applies medicines and dressings. The aim is to save the docto

LONG-TERM MEDICAL CERTIFICATES

NEW regulations laid before Parliament last week James Griffiths, Minister of National Insurance, allow certificates for sickness benefit to be given at longer i in cases of protracted illness. Hitherto a chronica person has been able to submit special intermediate certificates at intervals up to eight weeks—but onl was not seeing his doctor for examination or tr more frequently. The patient who had to see his every week for a renewed prescription or an inject to submit weekly certificates, though both the doc the patient knew that the illness was going to last a lo

The new regulations, which came into operation on extend the intervals at which a special intermediate certificate may be given in cases of protracted illne eight weeks to thirteen weeks, and enable such cer to be given even though the sick person is being e or treated by the doctor more frequently. This down some of the routine certification work of doct will also reduce the number of times the patient has documents to the local National Insurance office.

The regulations have been made provisionally pe report on them by the National Insurance Advisory Co The committee will consider objections to them wl sent before Aug. 26, to its secretary, at 6, Curzon London, W.1. The preliminary draft of the regulatio

TWENTY-FIVE YEARS OF BILIARY SURGERY*

WALTMAN WALTERS
M.D.
ON OF SURGERY, MAYO CLINIC, ROCHESTER, MINNESOTA;
ROFESSOR OF SURGERY IN THE MAYO FOUNDATION

1920–23, when I was a fellow in the Mayo Foundation, iagnosis of lesions of the biliary tract depended on valuation of a carefully taken history of the patient's s, and on the results of a physical examination. The ry was considered to indicate disease of the biliary when a qualitative type of food indigestion had red shortly after eating, particularly the gas- ing foods. This was especially important if attacks were pain in the right upper quadrant, or in the strium extending through to the back, were ciated with this indigestion. It was necessary to ide ulceration of the posterior wall of the duodenum, crisis-like attacks of pain; but the more frequent onse of this type of pain to ingestion of food, and the onstration of a crater shadow in the duodenal ulcer radiography, indicated that the lesion was in the denum.

arman's radiological demonstration of gastric and denal lesions was an outstanding contribution to gnosis at that time (Carman and Miller 1917). He attempted to demonstrate an abnormally functioning -bladder by using X-ray exposures of varying inten- . Kirklin (1922) described the clinical significance of ositive shadow in the region of the gall-bladder in ie cases of cholecystitis, and Rowntree attempted lisplay the gall-bladder by administering phenolated ogens, one of which (phenoltetrachlorphthalein) he l previously used to study the function of the liver el and Rowntree 1909). His test of liver function, proved by Rosenthal (1922), is still a valuable aid to determination of hepatic function.

n 1924 Graham and Cole began the study of chole- itography after intravenous administration of different mbers of the halogen group. They were able to show t concentration of the dye occurred in the gall-bladder, d that with X rays it could be seen either filling or ptying when normal, or failing to do so when diseased. adows made by gall-stones also would be shown in ny cases. Later, oral administration of the dye oved of great value in confirming a clinical diagnosis disease of the gall-bladder and likewise of excluding it. jaundice complicated the clinical history, if it followed attack of pain in the right upper quadrant of the domen and was fluctuating, a stone obstructing the mmon duct was suspected; for such stones seldom st an X-ray shadow. If the jaundice was painless, intrahepatic disturbance was distinguished from an structive lesion of the pancreas, of the ampulla of ater, or of the duct itself, by the presence of bile the stool in the former and its absence in the tter.

These clinical evaluations still form the basis of most rrect diagnosis of biliary tract lesions. Laboratory sts, now as then, have their greatest value when the sults are reviewed in connexion with the patient's story of his disease and with the findings at the time physical examination. One reason for this is that in any cases stones are present in a diseased gall-bladder ut are not demonstrable by cholecystography, although e disturbed function of the gall-bladder is evidenced y poor concentration of dye, and gall-stones may e present in a gall-bladder that fills and empties atisfactorily at the time of cholecystography.

The lay public began to recognise the value of laboratory procedures in the diagnosis of specific diseases, and not infrequently a patient who was having symptoms from a mild degree of dysfunction of the gall-bladder asked whether or not "X rays of the gall-bladder show stones."

TESTS OF LIVER FUNCTION

I have referred to the Rowntree-Rosenthal test which in the '20s was about the only good test for determining the function of the liver in the absence of jaundice. I have also spoken of the clinical methods used twenty-five years ago in the determination of the cause of jaundice. Noteworthy advances have been made in the last few years in studies of hepatic function and hepatic disease, particularly in cases of jaundice. Here again, however, the tests are valuable when used in conjunction with the better-known clinical methods of determining whether the jaundice is intrahepatic and non-amenable to surgery or is due to an extrahepatic obstruction, in which case surgical treatment is urgently needed. I should like to emphasise, however, that no single laboratory test can be relied on to give an index of hepatic function or to indicate the type of dysfunction present if the results of the test are contrary to those of other laboratory tests or clinical tests.

The laboratory helps to provide answers to four questions:

(1) Are other constituents of bile besides bilirubin present in the patient's serum? If so, there is a strong possibility of extrahepatic block.

(2) Does the blood contain an excessive amount of globulin, and is the albumin-globulin ratio reversed? If so, some form of degenerative or distinctive disease of the parenchyma of the liver is probably present.

(3) Does the bile reach the intestinal tract? If so, the likelihood of neoplastic obstruction is not great.

(4) Does the prothrombin-time fall promptly after the administration of naphthoquinone (vitamin K)? If so, the parenchyma of the liver cannot be totally destroyed and there may well be an extrahepatic block.

These individual problems will be considered briefly.

Blood lipids as a rule are increased in cases of obstructive jaundice and decreased in cases of severe hepatic injury. The study of cholesterol, cholesterol esters, and alkaline phosphatase in the serum is not entirely satisfactory because of technical difficulties. The simpler turbidimetric procedure of Kunkel (1947), involving a phenolsodium chloride solution, promises to give close agreement with the total lipid content; a high degree of turbidity is found in obstructive jaundice and normal levels in primary disease of the liver.

The gamma-globulin of the serum is increased in hepatitis and the serum-albumin is decreased. The cephalin-cholesterol flocculation test of Hanger depends on these changes. It not infrequently gives positive results in cases of obstructive jaundice. The thymol turbidity and flocculation tests are less subject to error. Kunkel has devised a still simpler and highly reliable method of checking serum-globulin by the use of turbidity which is consistently found in hepatitis; normal results are the rule in obstructive jaundice.

The two simple tests devised by Kunkel et al. (1948) may be used as a basic screening procedure of considerable value. The degrees of turbidity obtained with the two tests are usually roughly reciprocal one to another, and, as Maclagan (1944) said of simultaneous determinations of alkaline phosphatase and thymol turbidity, these two turbidity tests will differentiate medical from surgical jaundice in about 3 out of 4 cases.

The best proof of complete occlusion of the bile passages is the demonstration of less than 5 mg. of urobilinogen in the fæces in twenty-four hours, and of

---

Donald Church Balfour lecture delivered at the University of Toronto on April 26, 1949

Royal College of Surgeons of England

At a meeting of the council held on July 28, with Sir Cecil Wakeley, the president, in the chair, it was decided on the recommendation of the Faculty of Dental Surgery to institute an annual dental lecture to be entitled the Lord Webb-Johnson lecture. Dr. J. Hall Best, president of the 12th Australian Dental Congress, was elected to the fellowship in dental surgery.

The Hallett prize for 1949 was awarded to G. R. Anderson (Queensland).

Diplomas of membership were granted to the following:

C. A. McCl. Aitken, G. W. Bainbridge, J. F. R. Ball, Qazi Abdul Bari, Eleanor H. Barrington, A. T. Barwood, Leon Bornstein, J. A. Blundell, I. I. Bornstein, Christine A. Bratt, J. E. Breese, Patricia L. Broadhead, D. E. Brown, H. J. Burns, R. A. Chesterfield, R. E. Citrine, E. G. Clarkson, K. R. J. Coates, Benjamin Crawshaw, P. J. Crosland-Taylor, J. R. Cross, Patricia A. Crowther, Thelma W. Dafforn, Brenda L. D'Arcy, D. M. Davies, I. B. Davies, Lorna C. Davies, J. G. Elliott, Gerald Ellis, Valerie M. Ellis, K. A. Etherington, M. N. Fergusson, Barbara M. Fessey, O. O. F. Ffooks, Gordon Fleet, E. A. Foreman, W. G. C. Forrester, Yvette A. P. Franklin, Raymond Gathercole, Patricia M. Gilbert, H. S. Glatt, Helen Gordon, Hugh Gough-Thomas, S. S. Grové, A. O. Hagger, R. E. Hancock, Josephine Harper, W. H. Harper, P. H. R. Hawkes, K. M. Herd, Patricia Herdman, J. J. B. Hobbs, T. H. Hughes, Sheila M. H. Hugh-Musgrove, Margaret M. Ives, Harry Jackson, O. H. James, W. B. Jennett, C. H. Jones, Peter Kelly, Ian Kent, D. S. Kerr, Ann Kiln, W. B. Knapman, N. B. Kreitman, Kazimierz Kuczynski, J. W. Latham, Mary I. Legg, J. C. Linn, H. K. N. Lister, Marcia McArthur, John Mander, W. K. Marshall, Pamela G. L. W. Mason, Shanti Narain Mathur, D. G. May, Jit Shrimukh Mehta, Margaret L. Meikle, R. R. Middleton, J. B. Millard, D. D. Miller, K. E. Mortimer, G. M. Muller, Q. F. Neethling, N. H. Newman, R. L. Newman, G. J. Nicholas, D. H. Nixseaman, P. L. Norman, C. P. B. Parry, P. T. Perkins, C. D. Peters, S. T. H. H. Pilbeam, K. N. J. Pocock, C. O. M. Priday, Suzanne L. Quittner, Joscelen Ransome, J. A. Rassell, Regina Reif, W. M. Savery, Helmuth
ld, E. M. Sklar, June M. Smith, Susan
J. G. Sowerbutts, G. D. Stones, Medora
Frederic Tavill, J. M. Thomas, P. W.
I. M. Webster, Jean I. Whittle, W. B. M.
Young.

The following diplomas were granted jointly with the Royal College of Physicians:

D.P.H.—Bashir Ahmad, Bashir Ahmad Bhatti, Mary Brooks, T. H. Elias Griggs, W. E. Hadden, D. G. Levis, Gim

D.T.M. A. F. H. Stewart, S. W. W. Terry.

D.M.R.D.—D. Chisholm, J. J. Wallis.

Royal College of Surgeons of Edinburgh

At a meeting of the college on July 27, with Mr. Frank Jardine, the president, in the chair, the following were admitted to the fellowship:

C. E. L. Allen, Frederick Baar C. S.
Campbell, Burjor Cavas Dastur, Pa Drum-
mond, J. M. E. Jewers, D. H. King ePhee,
J. J. MacPherson hmoud
Ahmed Radwan, ussein
Saadi, Nagaling Humara Sayeed,
Rabindra Naray M. Stratton, P. A.
Thorpe, H. S. Tr

Scottish Conjoint Board

Having passed the final examination, the following have been admitted licentiates of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow:

A. E. Barr, Margaret H. Batty, Constance E. Bolton, W. E.
Bennie, M. nan, D. G. Brown, E. L. R.
Brown, W. Cargill, S. L. Chinchin, L. I.
Davidson, Daya, James Devine, D. J.
Docherty, E. Ferguson, L. M. Foegal,
Vincent Gallone, G. T. W. Gowdie, Joan F. Greaves, Muriel S. Hill,
D. D. Hillier, J. B. M. Hirst, Harold Jackson, James Jackson,
R. G. Jacomb, Ruth W. Joelson, Valerie
J. D. Keir, Rosemary C. Kennedy, R. C. L
, D. B. Murray, R
Page, Basil Raebu
itz Starer, Cornelius
T. H. Walker, B. T.

Royal Appointment

Surgeon Rear-Admiral F. G. Hunt, C.B.E., has been appointed honorary physician to the King in place of Surgeon Rear-Admiral J. A. Maxwell, C.V.O., C.B.E., who has retired.

Nuffield Foundation Visitors

The panel chosen this year to visit the Colonies as informal and unofficial consultants is as follows: Dr. E. R. Cullinan, Prof. R. C. Browne, Sir Stewart Duke-Elder (East Africa); Dr. Robert Lees, Prof. B. G. Maegraith, and Prof. R. W. B. Ellis (West Africa).

Royal Institute of Public Health and Hygiene

On July 21 Mr. W. E. Tanner, chairman of the e committee of the institute, presented the Harben Lord Boyd-Orr, M.D., F.R.S., formerly director-general United Nations Food and Agriculture Organisation, Smith award to Dr. M. T. Morgan, medical officer of for the Port of London.

Typhus in Afghanistan

News of a louse-borne typhus epidemic in Afg has reached the World Health Organisation thro regional office at New Delhi. This office is sending and D.D.T. to Kabul, and the Washington regional of the Pan-American Sanitary Bureau has supplied ad vaccine direct.

London Executive Council

At a meeting of this council on July 28 it was that payments during the first year of the National Service totalled £8,648,185 and that the administratio was only 1·25% of the whole. Details of the exp are: medical services, £2,627,614; dental services, £2, ophthalmic services, £1,693,767; pharmaceutical £1,918,188; administration, £108,084. The number of tests made in the year was 702,916, and the amount ophthalmic services is only for glasses actually dispe

Remuneration of Hospital Nurses

In a memorandum to hospital authorities the of Health says that considerable numbers of nurses hitherto been employed in hospitals at rates of remun and under conditions of service which do not accord the recommendations of the Rushcliffe Committee; has been notably the case where nurses have been em through the agency of nursing coöperations and organisations which themselves fix fees and charge missions." Now that rates of remuneration have settled by the Whitley Council for certain classes of the Ministry deems it essential that all arrangements aff these classes which are not in accordance with the rates and conditions shall be quickly brought to a "In no circumstances should any new nursing st engaged after the receipt of this memorandum on differing from those recommended by the Rushcliffe Com or agreed by the Whitley Council, as the case may be

Beit Fellowships for Medical Research

Sir Alfred Beit has resigned from the board, and Mr. Hornby has been elected as a trustee in his place. Simonds has been elected a trustee in place of the late du Parcq. The following awards have been made:

JUNIOR FELLOWSHIPS

D. V. BATES, M.B. Camb. To carry out research on resp function: at the Dunn laboratory, St. Bartholomew's H London.

Oxfd. To study the mechanism
pituitary hormones: at the de
anatomy, University of Oxford

B. CINADER, PH.D. Lond. To investigate the format multiple antibodies to a single antigen and to examin properties: at the Lister Institute of Preventive Medicine,

J. T. DAVIES, PH.D. Lond. To investigate the nature excitation of living cells by examining the closely similar built-up films of materials which recent work suggest to be sible for the permeability of cell walls: at the Royal Insti London.

D. T. ELMORE, B.SC. Lond. To examine the hydroly nucleic acids: at the university chemical laboratory, Cambr

A. S. JONES, PH.D. Birm. To study the immunochemi bacterial nucleic acid complexes: at the A. E. Hills labora chemistry department, University of Birmingham.

JUNE LASCELLES, M.SC. Sydney. To study the metabolic f of folic acid and *p*-aminobenzoic acid: at the departm biochemistry, Oxford University.

E. REID, B.SC. Aberd. To study the pituitary growth horm relation to metabolic processes: at the school of bioche University of Cambridge.

B. D. WYKE, M.B. Sydney. To carry out quantitative stu the electrical activity of the brain in patients with central system disorders: at the department of surgery, University of and Radcliffe Infirmary, Oxford.

Course on First-aid

A fortnight's course on first-aid and home nursing is to on Sept. 3 at St. John House, 15, Collingham Ga London, S.W.5, under the direction of the St. John Amb Association. Further particulars may be had fro warden.

patectomised dogs could be kept alive for several y the intravenous administration of glucose, was given intravenously to jaundiced patients. as, with an adequate intake of protein, and trans- of blood when necessary, were of the greatest making these patients better risks for operation. ar programme carried out after operation was of mportance.

l fields of surgery, when one's interest is engaged particular problem, and there is opportunity to and operate on an increasing number of patients, l judgment and the technique of operation e. In my experience my desire to approximate ls of the common duct after the excision of a stric- s led to a more diligent search for the lower end of mmon bile-duct in recent years, which has been ed by choledochocholedocostomy (union of the the duct) in a much higher percentage of cases had previously achieved. Moreover, since I ised that it should be possible to find at least a of hepatic duct beyond the liver, I have been find one on many occasions, though at first, after ng the hepaticoduodenal ligament, there seemed o portion of the unstrictured hepatic duct beyond ver. By dissection into the hilus of the liver, ntly a narrow rim of duct can be identified. Then ction on this with Allis forceps the parenchyma of er can be dissected away for a sufficient distance, t the duct is long enough to be anastomosed to the num in most cases. In 9 cases in the early series 13 in the later, I was able to find a dilated intra- c duct by insertion of an aspirating needle at m in the vicinity of the hilus of the liver. When duct was found an incision was made into the substance along the needle and a catheter was uced to drain the intrahepatic ducts effectively. In l of these cases the pressure of the catheter against de of the duodenum after operation produced a opening in the duodenum, and an internal fistula ped between the intrahepatic opening and that in odenum. Six cases of this type have been reported arvin and me (1948).

operations which I have described for use in the nent of stricture of the common and hepatic in spite of the seriousness of the lesion and its ications have given the following results:

f the patients on whom choledochoduodenostomy, aticoduodenostomy or choledochocholedocostomy was ormed from 1924 through 1939 at the clinic, approxi- ely 62% were living and well at the time of follow-up 940.

f the group who had sufficient common duct above the ture, so that anastomosis to the duodenum was per- ned, approximately 80% were living and well (Walters Phillips 1949).

CLINICAL AND LABORATORY INVESTIGATIONS

iscussion of stricture in cases of obstructive jaundice s me to refer to the opportunities for clinical and imental investigation in such cases and the practical ability and sometimes the far-reaching value of studies.

eral years ago, in dissecting the stump of the ic duct from the liver in order to give it sufficient to anastomose it to the duodenum, a small ng was inadvertently made in the duct above the omosis. Leakage of bile occurred from this opening. bile accumulated below the liver and was in turn ovement of the diaphragm drawn above the liver. en depressed and rotated the liver in such a way the circulation of the inferior vena cava was inter- with and a shock-like condition resulted. This tion was characterised by an increase in pulse and atory rates and a drop in blood-pressure. The nt's incision was opened in her room the evening of the operation and bile was seen to gush from above the liver. After this the patient's pulse and respiratory rate decreased progressively and rapidly, the blood-pressure rose, and she recovered within a few hours from the shock-like condition, and in a normal period from her operation.

The depression of the liver intrigued my first assistant, Dr. Kilgore, and we discussed the problem with Dr. J. L. Bollman of our Institute of Experimental Medicine (Walters and Bollman 1928). He suggested that we study the problems in the laboratory by placing a rubber glove above the liver. When the glove was inflated with air, the liver was depressed and had partially rotated around its ligaments; it occluded the returning circulation from the inferior vena cava and the same changes in pulse and respiratory rate, and blood-pressure occurred as had occurred in the patient. We could reproduce the shock-like condition at will by either depressing the liver or clamping the inferior vena cava.

A few years later bleeding from the gall-bladder fossa in a jaundiced patient caused the blood to accumulate above the liver. When it clotted, the liver was depressed and rotated. Although the patient's condition was extremely serious as a result of the shock-like conditions which have been described, she was brought to the operating-room, the incision was opened, and large clots were removed from between the liver and the diaphragm. She improved immediately and recovered completely. I might say that she had not lost an excessive amount of blood, and loss of blood was not responsible for her shock.

In this regard Dr. Bollman has told me of the studies made during the war on the causes of blackout among the dive-bombing pilots or among subjects exposed to centrifugal force in the human centrifuge as well as in an airplane dive. In both circumstances some downward drag and partial rotation of the liver occurred, which was partly responsible for the drop in blood-pressure, and the decrease in the blood draining from the abdomen and lower extremities to the heart, evident in blackout. The blackout or shock-like condition was counteracted in part by the wearing of a very tight abdominal belt which prevented the descent of the liver. More recently descent of the liver has been further prevented by having pilots assume a reclining position.

Another problem which intrigued me arose in cases where biliary stricture was so complete that the only treatment possible was introduction of a catheter into one or both intrahepatic ducts. When catheters were introduced into both ducts we were able to compare the output of bile and its constituents, bile pigment and bile salts, from the two lobes of the liver, and to compare the findings with regard to the proportionate size of liver, the amount of obstruction to one or both ducts, and the rapidity of recovery. Of practical importance is the fact that although the estimation of bile salt in the bile is a better indication of hepatic function than of excretion of bile pigment, yet the latter is a rough and reasonably accurate means of determining liver function. In other words, the excretion of a normal amount of normal-coloured bile from the liver indicates good function.

In recent years the pathological physiology of the common bile-duct has attracted the attention of observers in many countries. Included among them are Mirizzi (1933) of Cordoba, Argentina, Bergeret and Caroli (1947) of Paris, Mallet-Guy et al. (1947) of Lyons, France, Best (1937) of Omaha, Nebraska, Overholt (1931) of Boston, McGowan et al. (1936) of Rochester, Minnesota. Several years ago McGowan and Butsch, when they were working with Gray and me, became interested in studying pressure within the common bile-duct of patients who had had attacks of seeming biliary colic after cholecystectomy and in whom stones in the common duct were not found at secondary operation. By the introduction of a complete absence of urobilinogen in the urine. These studies are exacting and difficult for general use. Duodenal drainage if carefully done gives about the same information, provided that the position of the tube is checked by screening.

Quantitative data on the degree of hepatic damage in the presence of jaundice are difficult to obtain. Determination of the rate of synthesis of hippuric acid, at one time believed to be a reliable guide to liver function, has been largely abandoned. The response of an elevated prothrombin-time to vitamin K gives useful information in this respect, since a prompt response implies a fairly large number of functioning liver cords. If any reasonable response is obtained, it suggests the presence of fairly good hepatic parenchyma and an extrahepatic block.

Where the laboratory aids mentioned give discordant results or data at variance with the history and physical findings, biopsy of the liver with the Vim-Silverman needle may prove extremely helpful. It is especially useful in distinguishing the various residues of infective (viral) hepatitis and is always worth considering if such a condition is suspected. In my opinion it should be done under surgical supervision because of the danger of hæmorrhage.

CLINICAL EVALUATION

I have referred to the development of cholecystography and should like briefly to evaluate it when it is used in present methods of examination. At the Mayo Clinic great dependence is placed on the cholecystogram which demonstrates abnormal function, and equal importance is attached to the cholecystogram which discloses normal function in a case in which there is no history of disease of the biliary tract. When, however, there is a history of typical biliary colic, or a history of gaseous dyspepsia that has persisted in spite of attempts at control by medical means, we believe that surgical exploration of the biliary tract, as well as exploration of the stomach, duodenum, and appendix, is advisable, even though radiological studies of the gall-bladder, stomach, and duodenum do not disclose any abnormality. Mention is made of the stomach and duodenum because an ulcer on the posterior wall of the duodenum which has perforated into the pancreas frequently produces œdema of the head of the pancreas, with secondary disturbance of motility of the pancreatic portion of the common bile-duct and a mild degree of jaundice. Conversely a diseased gall-bladder may produce symptoms that mimic in some respects those of peptic ulcer. This is due in part to associated gastrospasm or pylorospasm. In addition the diseased gall-bladder may produce gastro-intestinal bleeding in the absence of gastro-intestinal ulceration. The reasons for this are not entirely clear.

When the patient gives a history of biliary colic, the decision as to whether surgical treatment should or should not be employed ought not to be too greatly influenced by the absence of gall-stone shadows or the number of gall-stones appearing in the X-ray film; for there is at least a 10% error in this respect.

In recent years there has been an unfortunate tendency to deny operation to patients who have had symptoms of cholecystitis but who do not appear to have any stones in the gall-bladder on radiography. This may be due to the publication of papers on the so-called medical treatment of cholecystitis. The fallacy of withholding operation from this class of patients is apparent in view of the foregoing discussion. To allow a patient who is in good condition, except that he or she has cholelithiasis, and for whom the risk of cholecystectomy is less than 1%, to proceed to the point of experiencing acute obstruction of the cystic duct or of the common bile-duct, with resulting complications which increase the risk of operation and reduce the completeness of the surgical cure, seems to be unjustifiable.

SURGICAL PROBLEMS FOR BENIGN CONDITIO

The relation of the hepatic artery and its
to the hepatic, the cystic, and the common b
varies more than any other anatomical relatio
the abdomen. Unless extreme care is taken in
the structures of the hepaticoduodenal ligam
anomalous hepatic artery or one of its branches
injured and infarction of the right lobe of the l
death may result. Likewise the attempt to contr
ing from such an artery blindly may result in a
to the common bile-duct at a very high level. So
the infection in the gall-bladder, with its extens
the hepaticoduodenal ligament, has produced s
induration and œdema that the anatomic mar
these structures are lost, and a segment of comm
is removed with the gall-bladder. In cases in w
degree of infection is great, and it has extended
hepaticoduodenal ligament, all but those skilled in
of the biliary tract would do well to be conte
drainage and removal of stones from the gall-
Cholecystectomy should be reserved until a lat
when the cholecystitis has subsided.

In the surgery of cholecystitis, one of the p
most distressing to me has been the increasing fr
with which it has been necessary to operate on
whose common bile-duct has been injured at t
of operation on the gall-bladder and a strict
resulted. This has necessitated an operation or op
of considerable magnitude on patients who are
good general condition. In many of these
previous unsuccessful attempts have been m
repair, not only once but often twice or three tim
sometimes four or five times.

My colleague, Snell, recently returned from a
the English medical and surgical clinics. He w
ticularly impressed with the infrequency with
stricture of the common bile-duct was seen in the
clinics there in contrast to our experience at th
Clinic.

While I am on the subject of strictures, I wish
that an accurate anastomosis restoring the
intestinal continuity is of the greatest importance
cases. If possible the ends of the duct should b
tomosed after excision of the stricture, or if
not possible the duct above the stricture sho
anastomosed to either the duodenum or the jeju

Generally speaking, the results of each type of op
will depend on the accuracy of the anastomosis a
degree of infection in the wall of the common bi
and within the liver (Walters and Friedell 1945).
tion in these structures, especially with associated
hepatic calculi, are the reasons, I believe, why cont
sometimes occurs later at the site of the anast
and another operation for relief of the obstruc
required.

In my first series of 98 cases in which operati
stricture was performed between 1924 and 193
mortality-rate was approximately 10% (Walte
Phillips 1949). In the second series of 88 cases in
operations were performed from 1940 to January,
the mortality-rate was 3·4% (2·6% per oper
This reduction in mortality-rate is a reflection
advances made in the treatment of patients with o
tive lesions of the biliary tract. Studies reveale
elevation of the prothrombin-time of the bloo
associated with a considerable degree of disturba
the liver and the tendency to hæmorrhage.
prothrombin-time could be reduced by the ad
tration of vitamin K or vitamin-K-like substance
reduction indicated that the liver cells were not
diseased. It was found that vitamin K also prev
serious postoperative bleeding. After the experin
work of Bollman, Mann, and Magath (1926), who s

for this reason the position of the needle in the should be fairly central.

oramen may face almost straight downwards, ı case the needle point may enter it only to jam its posterior lip.

ning the needle to be in the nerve and through men, we may be hindered in the fourth stage by er difficulty, which is well described by Van 921):

> ne gasserian ganglion is a very much flattened ure, and is so situated that its narrow margin is ted to a needle entering the foramen ovale. Should edle be introduced in a plane nearer to the vertical hat of the ganglion, it may readily enter the foramen, stead of proceeding on into the ganglion it will enter ibarachnoid space above it. Or, should the needle n a plane nearer to the horizontal, it will probably v beneath the ganglion capsule, where injection may de without effect."

writers ignore the dimension of this "narrow " Härtel (1914) gives it simply as 3 mm., que (1927) as "3 mm. at the most." The plexus laris where it merges with the ganglion is, if g, the thinner structure of the two, and is ly only 2 mm. thick. As it passes upwards and rds to the porus trigemini it becomes thicker s broad; but, on the other hand, the further dle point is advanced beyond the foramen ovale ater the effect of any slight error in direction.

ganglion and plexus rest closely on the anterior of the petrous bone, which in this region, apart he impressio trigemini, is flat. The needle, if it ay wholly within the ganglion and plexus, should allel with this flat surface. If there is any angle n them it must be a small one, which I propose ne the petrous-needle angle. Its value will be ith a correctly sloping needle, positive with one s too steep, and negative with one that is not nough.

ortunately the inclination of the anterior surface petrous bone is extremely variable. Zenker (1938) red the angle between it and a transverse plane g from the external auditory meatus to the root nose; he found this angle to be 55° in the longest and 90° in the shortest. Hence, if the petrous- angle is always to approximate to zero, the between the needle shaft and the horizontal must ary greatly from case to case.

Allen's analysis needs two additions: (1) by g very high through a large round foramen, or low through any foramen, a needle may run el with the anterior surface of the petrous bone et come to lie above or below the ganglion and s; and (2) a needle lodged right against the lateral edial margin of the foramen may have its point y near the corresponding border of the plexus. are two more reasons why the needle point should hrough the centre of the foramen ovale.

sum up the conditions for a well-placed needle :

The site of the skin puncture must be such that the between the needle and the anterior surface of the us bone (the petrous-needle angle) will be zero or nearly

The foramen ovale must be found, and entered lly.

The needle point must be advanced into the postero- or part of the plexus triangularis—i.e., 10–15 mm. d the foramen.

far we have dealt only with the problems inherent rmal cases. There are also some recognised abnor- ies which can cause difficulty or danger. A pterygo- us bar, though usually situated medially to the nen ovale, may lie across it and so be an obstacle. foramen ovale may be fused with either the foramen spinosum or the foramen lacerum. Härtel (1912) discusses these and similar anomalies exhaustively; Sunderland (1938) gives an excellent account of them in English.

PREVIOUS METHODS

It would be strange if no-one had tried to solve any of these problems by a radiological demonstration of the needle in situ, and this has been attempted in several ways.

Pollock and Potter (1916), desiring an aid to Harris's lateral approach, inserted both a metal bougie into the eustachian tube and the needle into the cheek, and ascertained their relative positions by screening. For Härtel's approach they favoured screening in a lateral projection without the bougie.

A paper by Dorrance (1917) includes, without explanation, a lateral radiogram of a needle passed into the foramen ovale by the anterior approach. We are left to guess whether radiography played any part in his routine of injection.

Härtel (1920, 1921) described a projection in the axis of the foramen ovale, which could show the needle almost end-on. His work was repeated and confirmed by Goetze (1921). Sicard (1924) demonstrated three cases in which, immediately after the alcohol, he had injected 1 ml. of iodised oil and exposed stereoscopic films; the oil was found to have spread remarkably widely in the subarachnoid space. This, with scant justification, he called *contrôle lipiodolé*.

Dogliotti (1930) wrote: "It is often advisable, before attempting to enter the oval foramen, to take an X-ray picture of the base of the skull so as to obtain the exact position of the point of the needle." He described this procedure, which was to be carried out under light general anæsthesia, as "rarely necessary but always useful."

Stiasny (1933) for a while used a single projection, which seems to have been not unlike Härtel's.

Kirschner (1933) and Zenker (1934), who sought to destroy the gasserian ganglion by means of mathematics, machinery, and coagulating diathermy, stated that stereoscopic radiograms in the basal projection were occasionally helpful during their onslaughts; but soon Kirschner (1936) declared them unnecessary.

Brücke (1934) described a modification of Härtel's projection. Sgalitzer and Brücke (1934) admitted that this projection did not show the depth of the needle. Before the alcohol, therefore, they injected 0·5 ml. of a thin iodised oil and took a lateral radiogram. They saw the oil lying extracranially or intracranially, and so hoped to infer the position of the needle point.

Härtel (1935) had by now evolved a complex technique, which he described none too clearly. Using only his one original projection, he combined screening with repeated radiography of the needle at an unspecified number of slightly different angles. In his masterly hands the results were excellent.

Putnam and Hampton (1936) used "a roentgenogram . . . taken along the axis of the needle guide" (a brass sleeve inside which the needle proper was afterwards passed). In their published example, however, the exterior end of the needle guide is seen well above and to one side of the other end, which lies in the foramen ovale; presumably this displacement is unintentional and its direction and extent are matters of chance. They added: "It is advantageous to take a true lateral view also, to show the depth to which the guide has penetrated." The insertion of the guide and the radiography were performed under general anæsthesia.

Lemoyne (1946) has recourse to radiograms "if the foramen ovale is hard to find or if one has the least doubt about the precise position of the needle point." He uses two projections: a basal, and a lateral centred on the temporomandibular joint.

Adler and Gál (1948a and b), in an effort to rise above the present lack of X-ray films in Hungary, use a pure screening technique with two projections at a right angle.

By no means all of these workers describe the positioning required for their special projections. All their systems have drawbacks. Screening, so careful tests have convinced me, shows the needle shaft poorly and the foramen ovale not at all. It is a complication to be avoided, and if it is used without radiography there will be no permanent record of the needle position.

radiopaque substance through the T-tube which was inserted into the common bile-duct at the time of operation, and by varying the pressure within the duct, these observers were able to demonstrate that the spasm of the sphincter of Oddi and of the duodenum increased the intraductal pressure and caused the pain of which the patient complained. They also found in the study of different substances used to decrease the periodic increase in intraductal pressure that sublingual administration of glyceryl trinitrate was followed by decrease in intraductal pressure which they were able to demonstrate radiographically and by relief of the pain. In a recent visit to European surgical clinics I saw at a clinic of Bergeret in Paris, at the Hospital of St. Antoine, a unique method for radioscopic study of the activity of the common bile-duct at the time of operation. A technician lies inside an enclosed operating-table, and a port-hole in the top of the table contained a viewing screen which enables him to make observations on the filling and the emptying of the ducts when a radiopaque substance is injected into them during operation. Spot films were taken at the proper time for immediate development and demonstration to the surgeon of the size of the biliary ducts, their ability to empty, and the presence of a stone or other defects.

MALIGNANT LESIONS

I shall not say much now about the malignant lesions of the biliary tract, which are infrequent compared with the benign ones. But with modern methods of anæsthesia, preoperative and postoperative treatment, and the improvement in surgical technique, the attack on small localised lesions of the common bile-duct, and especially of the ampulla of Vater, has been astoundingly successful. This is particularly true of the obstructing lesions of the ampulla of Vater. My colleagues, Drs. Waugh and Clagett, performed a large number of radical resections of the lower end of the common bile-duct and the head of the pancreas and the duodenum during the war (Waugh and Clagett 1946). My other surgical colleagues at the clinic and I have contributed some cases to the series. In all, as reported by Waugh (1948) the average length of life following radical resection for carcinoma of the ampulla of Vater has been 24 months and several patients have lived beyond that time. On the other hand, when the malignant lesion involved the head of the pancreas, although a few patients have lived more than 14 months, the average length of life has been only about 8–9 months. In such cases, however, the patient's jaundice has been relieved and some of them have obtained relief of the pain associated with the perineural cancerous involvement in the head of the pancreas. The risk of this operation, however, is high and will vary from 15 to 20%.

In contrast are the results of the more conservative operation of the anastomosis of the distended gall-bladder or common bile-duct to the duodenum or jejunum. This procedure, which has a low risk, relieves the patient's jaundice and itching and prolongs his life: it is well worth while.

The two operative procedures which I have just mentioned have additional values. With the recognition that many such lesions are amenable to removal, the surgeon can offer the jaundiced patient not only relief of jaundice caused by most malignant lesions, but also the chance that the surgical exploration may reveal a benign rather than a malignant lesion. If the lesion is malignant, the jaundice and the itching can usually be relieved and in some cases the lesion can be removed.

COMMENT

In the past twenty-five years the picture has changed from one in which clinical judgment received little aid from laboratory procedures to one in which, although clinical judgment is still the most important fac determination of the diagnosis of the lesion location, the laboratory can give great help in id the type of jaundice present and assessing the of the liver. The improvements in anæsthesia, administration of blood, vitamins, fluid, and el have permitted greater accuracy and less speed in operations. As a result the lesion may be re possible and necessary, or if removal is not the biliary obstruction may be relieved at a l As preoperative treatment along physiological lowered the risk of operation, so postoperative along similar lines has promoted more rapid and together they have lowered the mortality.

A SIMPLE RADIOLOGICAL AID T GASSERIAN INJECTION

JOHN PENMAN
M.B. Lond., M.R.C.P.
NEUROLOGIST, HERTFORD COUNTY HOSPITAL; CLIN ASSISTANT, NEUROSURGICAL UNIT, ST. GEORGE'S H
LONDON

THE procedure discussed here is alcoholic g injection by the anterior approach of Hartel (In placing the needle for injection we can dist four stages:

(1) Putting the needle point into the foramen ovale, it must be remembered, is a short canal.

(2) Piercing the mandibular nerve.

(3) Passing the needle point through the foramen.

(4) Piercing the gasserian ganglion and the plexus angularis. There is good evidence (Cavina 1932) that postero-superior part of the plexus is the site where smallest quantity of alcohol will produce the req anæsthesia.

ANATOMICAL DIFFICULTIES

Given a small foramen facing in a favourable dir and just the right angle between the needle shaft the horizontal, the first stage may be followed e even inevitably, by the next two; but we do not see all these conditions fulfilled in one case.

A large foramen may contain not only the mandi nerve and the accessory meningeal artery but vein or venous network of considerable size (Lind 1936, Bergmann 1942), and so may admit the point without bringing it into contact with the No doubt it is possible for the needle to skirt the in this way and yet to penetrate the ganglion, but alcohol leaking back along the path of the needl be able to reach nearby intracranial structures. better for the needle point to bury itself in n tissue at the foramen and thenceforth to remain b

pretation

determine the position of the needle point, we first
ine the basal film (fig. 4). This projection shows
bearing directly and obviously. It understates the

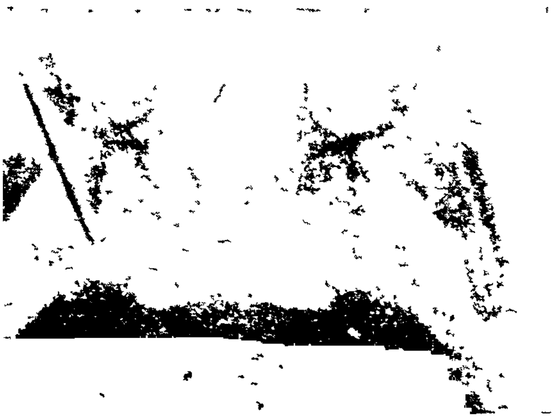

Fig. 4—Basal view.

depth because the angle it makes with the needle shaft is not the ideal 90° but usually much nearer to 45°. The divergence of the X rays and the ensuing magnification of the plane of the foramen ovale counteract this understatement, but not completely. In most cases the needle depth as measured on the film is to the true depth approximately as 4 to 5.

We now turn to the oblique film (fig. 5). As we saw during the positioning, this does not give a theoretically perfect view along the needle, because of the deliberate medial displacement of the mount. However, the silhouette of the foramen which it presents to the eye is practically the same as that presented to the needle point. The shadow of the needle shaft is horizontal, and therefore its elevation can be directly seen regardless of depth.

Combining these data, we know the position of the needle point in all three dimensions. The bearing and elevation are probably accurate within 1 mm. and the depth rather less accurate. Fig. 6 shows how this is achieved.

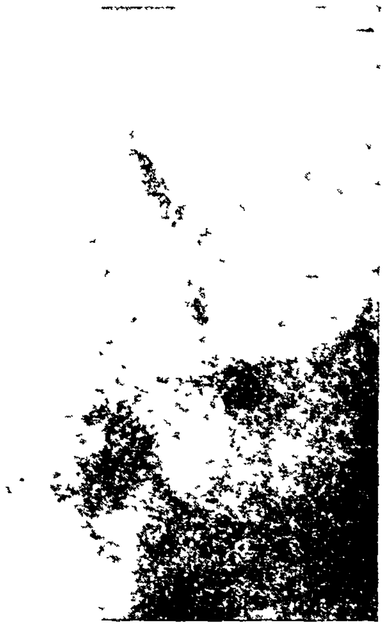

Fig. 5—Oblique view.

The petrous-needle angle must still be considered. In the oblique projection the central ray passes close to the ridge of the petrous bone before traversing the foramen ovale, and the film shows this ridge as a faint but definite horizontal line. The foramen may be partly hidden behind the ridge, just clear of it, or well above it (fig. 7), like the rising sun at various stages above the horizon. The petrous-needle angle is zero when the lower edge of the foramen seems to be just resting on the ridge. A positive petrous-needle angle will usually make the foramen appear more rounded, and a negative one more slit-like.

The two projections supply each other's deficiencies as follows:

Information required	*Given by basal projection*	*Given by oblique projection*
Depth	Yes	No
Bearing	Yes	Yes, when depth is known from basal view
Elevation	No	Yes
Petrous-needle angle	No	Yes
Shape of foramen as viewed along needle shaft	No	Yes

Adjustments

The needle can now be moved. If the petrous-needle angle is at all far from zero, a higher or lower point is chosen for the skin puncture. If the needle has not entered the foramen, or has entered eccentrically or to a wrong depth, either it is adjusted, or it is left and a second needle is introduced beside it. As mentioned by Härtel and by Putnam and Hampton, the first needle, its position being accurately known, is a valuable guide to the second.

The radiography of unconscious patients is undesirable. Lateral projections do not show the foramen; they therefore give only a rough notion of the depth of the needle, and no notion whether its position in the foramen is high or low.

A perfect end-on view of a correctly placed needle would defeat its own object, for the mount of the needle would mask both its shaft and the foramen. Where the projections are inadequate, iodised oil does little to improve them, informative though it may be in other ways. Stereoscopic films are elaborate and cannot usually be viewed in the wet state; they offer a three-dimensional picture of a sort, but it is a subjective and feeble sort, not to be compared with the certainty of two projections at a right angle. On the one hand, more than two pictures are superfluous, and, on the other, a single projection is not enough.

Above all, the proper function of radiology is not, as all but one of these writers imply, to guide the needle to the foramen ovale. Reasonable experience and care, without technical devices, should be enough in this first stage. Härtel (1933) realised this: "In these days I am no longer concerned with the problem of hitting the foramen ovale fair and square; that goes without saying. Instead I am concerned with finding the most central part of the gasserian ganglion." He, alone of the workers mentioned, states that his aim in using X rays is to refine his existing technique and to make sure of placing the needle in the centre of the foramen.

As for the thinness of the ganglion and the consequent importance of fitting the needle to the surface of the petrous bone, I have found no exposition of a radiological technique which refers to these points.

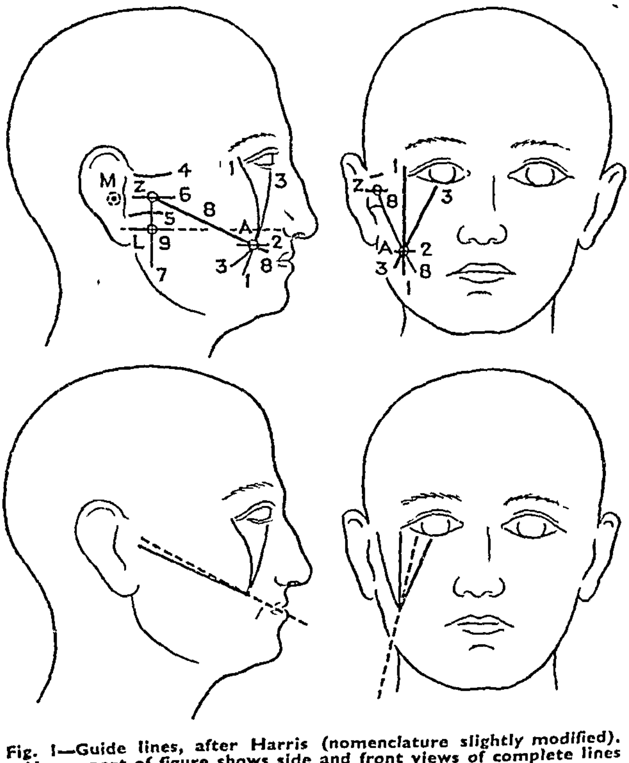

Fig. 1—Guide lines, after Harris (nomenclature slightly modified). Upper part of figure shows side and front views of complete lines for both anterior and lateral routes (numerals indicate order in which lines are drawn); 1, parasagittal line; 2, anterior cross line; 3, pupil line; 4, upper zygoma line; 5, lower zygoma line; 6, middle zygoma line; 7, coronal line; 8, elevation line; 9, lateral cross line; A, anterior point; L, lateral point; M, meatal point; Z, zygoma point (MZ = 2·5 cm.). Lower part of figure is an abstraction of the foregoing, showing only three essential lines for anterior route, with initial direction of insertion of needle.

PRESENT METHOD

Starting from the site of the skin punc borrowing two useful terms from gunnery, w that the needle point has a depth, a bearin elevation. Two ordinary radiograms in suita projections ought to give all this information. one projection should be perpendicular to t shaft to give the depth, and the other alon to give both bearing and elevation, but certain modifications will be possible. The pe projection can be rotated, so to speak, about of the shaft until it too shows either the be elevation. Each projection must also outline th ovale, which will then serve as a "grid" or frame, and the position of the needle poin completely determined. There remains the needle angle, to which we shall return.

So much for theory; the practical routine is as Preliminary films of the skull are exposed and s the basal film in particular may give warning of abnormalities. For injection the patient, withou medication, sits in a high-backed chair in the room. The guide lines advocated by Harris (193 drawn (fig. 1), and his modification of the ar approach is used.

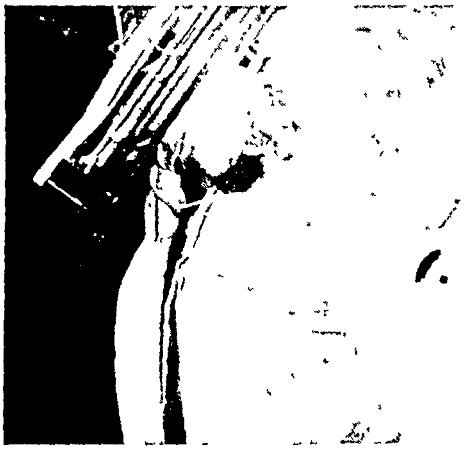

Fig. 2—Positioning for basal view.

When the needle point seems to be in the foramen minutes after puncture of the skin, whichever is s the patient sits on a stool at the X-ray apparatus. the best results this must be of the Lysholm-Schon type, which among many advantages allows the and the head table containing the film, to be r together about one horizontal axis. Two films now to be exposed.

Positioning and Exposure

Basal View.—The first film gives a modified view, the path of the central ray being parallel wi usual path but a little further forward and to the side of injection so as to pass through the fo ovale. This position is quickly found. Looking head from the side, one brings the zygoma point 1 and 2) into the same transverse plane as the c ray; looking from the front, one moves the head lat until the path of the ray lies in the same paras plane as the centre of the eyeball on the side of inj

Oblique View.—For the second or special oblique the patient has only to turn towards the side of inj through about 140°, so that he nearly faces the table, and to lift his chin as high as he can. A wedge-shaped cushion is put between the table his chin, so that the needle mount is held just of the table; by pressing his chin into the cushi steadies his head. The elevation line (figs. 1 and is a trend it is towards the cumulative success-rate %. In group 2 there is a steady upward trend, may well be due to increasing experience not of rian injection but of radiology as applied to it.

oup 1 includes 6 injections in which success was ved by the lateral approach through the sigmoid of the mandible, and in 3 of the 6 this was the approach tried. Since the introduction of the logical method the lateral approach, which is suited to it, has been tried only a few times, and

TABLE I—ANALYSIS OF INJECTIONS

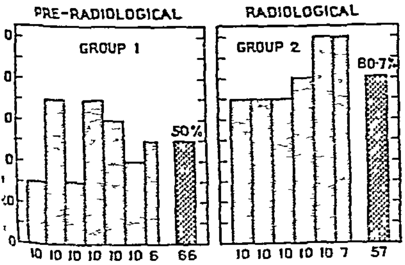
er successfully. If these facts influence our comparison ll, they can only favour group 1.

o distinction has been drawn between patients had already been injected by other workers and se who came with untouched ganglia. "First injec-t" means a first injection from me. All injectors other people's failures rather more difficult than h cases; the probability of an anatomical abnormality reater, and the previously injected alcohol may have sed fibrosis. Both in group 1 and in group 2 the cess-rate is a little higher if only fresh cases are en, but the difference is unimportant, and nothing uld be gained by complicating the tables with it.

Both these success-rates of 50% and 80% may seem atisfactory, but they are artificial and have no close ation to the patient's idea of success. The follow-up examinations have shown that technically inadequate degrees of sensory impairment may be followed by long periods of relief. Patients to whom only procaine injections could be given may be free from pain, and may even believe that eir faces are numb, for many months. A number of e two-day failures might easily have been called successes immediately after injection. Such facts must be membered by anyone seeking to compare these results ith those which other workers have obtained from uestionnaires. This is not to deny that the ideal result permanent anæsthesia to all stimuli in all previously ainful areas.



8—Two-day success-rates by separate tens of njections. Hatched columns show percentages or whole groups.

To the patient, what matters is whether after an jection he will want further radical treatment, and, if o, how long afterwards. The need for such treatment s the best criterion of a complete relapse. In group 1, 7 first injections for tic douloureux had to be followed y second injections or by sensory rhizotomies; in roup 2, no first injections have yet had this sequel. The following figures (which include 2 of the 4 early cases reviously mentioned as unclassifiable) give the details:

	Group 1	*Group 2*
All first injections for tic douloureux	58	33
Died in less than 3 months	1	0
Not yet followed for 3 months	0	5
Potentially in need of further radical treatment within 3 months	57	28
Given further radical treatment within 3 months ..	10	0
Not given further radical treatment within 3 months ..	47	28
Died in 3–6 months	2	0
Not yet followed for 6 months	0	3
Potentially in need of further radical treatment in 3–6 months	45	25
Given further radical treatment in 3–6 months	4	0
Not given further radical treatment in 3–6 months ..	41	25
Died in 6–12 months	1	0
Not yet followed for 12 months	0	11
Potentially in need of further radical treatment in 6–12 months	40	14
Given further radical treatment in 6–12 months ..	3	0
Not given further radical treatment in 6–12 months ..	37	14
All patients given further radical treatment after first injections	17	0

By this criterion we find that in group 1 the complete relapse-rate three months after a first injection for tic douloureux is 10 out of 57 (17%); in group 2 so far, with 28 cases, it is nil.

Though significant, these statistics convey but little of the precision, confidence, and power to reassure the patient which radiology confers. The average time devoted to an injection may be somewhat increased, but the time which patients have to spend in pain or suspense is greatly lessened. One can inject people whose fortitude would otherwise be insufficient.

Besides helping at the time of injection the radiograms are valuable in conjunction with the follow-up, and this value will grow. As more long-term results are obtained and correlated with the needle positions which produced them, it should be possible to discover more exact limits of depth, bearing, and elevation within which the chance of success will be high.

LIMITATIONS

Not all X-ray departments are suited to this work. From the radiographer it demands experience of skull radiography, interest, speed, and a readiness to take several pairs of radiograms at unpredictable moments. From the injector it demands tolerance and understanding of the radiographer's difficulties.

A few very elderly patients, when confronted with the X-ray apparatus, present a combination of deafness, bewilderment, and stiffness of the cervical spine which makes the method hard to apply. In some of the same patients, and rarely in less elderly ones, the skull is so decalcified that one cannot outline the foramen ovale

TABLE II—SEQUELS TO INJECTIONS

Freedom from tic for 12 months or more ..		(21)		(14)	(35)

Cases of tic douloureux in parentheses.

The time required for positioning, the two exposures, development, and interpretation is 10–15 minutes. The adjustments to the needle seldom take more than a few minutes. One pair of films is invariably exposed as a record of the needle position finally used for injection. Even for the most difficult cases three or four pairs of films nearly always suffice. The total time spent on an injection is more than would be spent by non-radiological methods in the easiest cases. It is probably rather more in those moderately difficult cases which form the majority, but in very difficult cases it is much less.

RESULTS

Between December, 1945, and March, 1949, I tried to give 135 alcoholic gasserian injections to 115 patients, 96 of whom had tic douloureux. These figures include every sort of failure, even 1 in which at an early stage of the injection, when there was every prospect of

We are left with 66 pre-radiological injection
short-term comparison with 57 radiological ones.

Criteria of Success

Trigeminal injections must be judged on
tests of sensory function made by the same obser
set intervals. In nearly every case in which at
sight the injection appeared to be a success I
examined the patient on the second day after inje
then at lengthening intervals up to the eighth
again at lengthening intervals up to the sixth m
and thereafter twice each year. My definition of su
for the purpose of this paper, is that at least in a
areas where pain had been previously felt there s
be analgesia, or some greater degree of sensory l
pinpricks. According to the interval after injecti
which this definition is fulfilled we may speak of a
day or an eight-week success. It has been possil
classify every injection, except the 4 early ones ment
above, as a two-day success or failure; 72
classifiable also on the eight-week basis.

The total number of two-day successes was 79
test the validity of this criterion of success, w
observe the sequels to these injections (table II)
figures in parentheses again refer to tic douloureu

From table II we see that of 72 two-day
69 (96%) were also eight-week successes, and th
37 eight-week successes in tic douloureux 35 (
were followed by freedom from symptoms for t
months or longer. These not very large numbers su
that in *tic douloureux* a two-day success, as de
here, means a 90% chance of at least a year's con
relief. It seems justifiable to take the two-day su
rate as a basis of comparison between the
radiological and radiological groups.

In fig. 8 these two groups are divided into batch
10, and the percentage of successes in each bat
shown separately. The cumulative success-rate is
shown at the end of each group. It will be seen tha
highest rate in group 1 (70%) is the same as the l
in group 2. It cannot be argued that the superi
of group 2 is merely due to increased experience
the fluctuations in group 1 appear to be random

this method of calculating the death-rate does not the risk of dying from a primary infection, for in irst year the number of children infected is small ared with the number infected between the ages of 1 10 or 10 and 15.

TUBERCULOSIS COMPARED WITH OTHER CAUSES OF DEATH

ie pædiatrician compares mortality from tubercu- in children with mortality from other diseases hildhood, rather than with total mortality from rculosis in the community. In table II the number eaths from tuberculosis for 1945 is set beside the ber of deaths from all causes in the same age-groups. ill be obvious that a comparison for the entire period years gives a false impression; for the large rity of deaths from other causes take place in the year, at a time when deaths from tuberculosis are eedingly few. The real significance of tuberculosis is arent in the period 1–15, when it is responsible for % of all deaths.

E II—DEATHS FROM TUBERCULOSIS COMPARED WITH ALL DEATHS IN AGE-GROUP (ENGLAND AND WALES, 1945)

Age-group	Deaths, all causes	Deaths, tuberculosis
0–1 year	31,959	307
1–5 years	6441	1004 (15%)
5–15 „	5898	897
—	44,298	2208 (5%)

THREE AGE-GROUPS

uring 1945 the 307 tuberculosis deaths in the first r form a very tiny fraction of the total 31,959 from causes. There are, however, in this first year many ses of death—prematurity, birth injury, and neonatal eases—which are not operative in other years and ich indeed are largely limited to the first three months. 1945 in these first three months deaths from tubercu- is were very few indeed, being only 22 among 22,580 ths. After this very special period of the first year deaths from tuberculosis increase, being 65 at months and 220 at 6–12 months. Thus of 9379 ths at 3–12 months in 1945, 285 or 3% were due to erculosis. Their place, relative to the chief causes of th at this period, is set out in table III, which shows,

BLE III—CHIEF CAUSES OF DEATHS IN INFANTS 3–12 MONTHS (ENGLAND AND WALES, 1945)

Bronchitis and pneumonia	3767
Enteritis and diarrhœa	1902
Congenital malformations	716
Whooping-cough	301
Tuberculosis	285
Accidental mechanical suffocation	280
Measles	238
Meningococcal meningitis	155

en all allowance is made for the difficulty of certi- ation at this age, the overwhelming importance respiratory infection and illnesses associated with arrhœa and vomiting. But it also shows that in 1945 berculosis killed as many infants as whooping-cough or easles, and nearly twice as many as meningococcal eningitis.

In table IV the six most important causes of death in e age-groups 1–5 and 5–15 years are displayed. In 45 these causes were responsible for 72·2% and 69% all deaths in the age-groups. In that year tubercu- sis was the third most important cause of death tween the ages of 1 and 5, and in the school years of -15 it was second only to death from violence and cident, being by far the greatest cause of death from fective illness. Indeed, at school age, accident and tuberculosis were together responsible for 48% of all deaths. If we then consider the death-rate from tuberculosis under the age of 15 in comparison with the death-rates from other infectious diseases as given in table 9 of the Registrar-General's Statistical Review and here set out as table V, the importance of tuberculosis is again seen. In this connexion it is interesting to recollect that in the epidemic of anterior poliomyelitis in the summer of 1947 only 267 deaths were recorded under the age of 15 years (Gale 1948). When we think of the widespread anxiety caused by this epidemic, and of the fact that more than 2000 children a year still die from tuberculosis without any apparent public concern, there seems to be need to see the disease in a new perspective and to realise that in England and Wales tuberculosis is still the most lethal disease in children of school age.

TABLE IV—CAUSES OF DEATH IN CHILDHOOD BEFORE AND AT SCHOOL AGE (ENGLAND AND WALES, 1945)

Cause	Ages 1–5 yr.	Cause	Ages 5–15 yr.
Total deaths	*6441*	*Total deaths*	5898
Respiratory disease	1325	Violence	1815
Violence	1162	Tuberculosis	897
Tuberculosis	1004	Dis. digestive system	466
Dis. digestive system	528	Respiratory disease	361
Measles	380	Diphtheria	331
Whooping-cough	254	Rheumatic fever	203
—	4653	—	4073

STATISTICS FOR NEWCASTLE-ON-TYNE

The problem in any particular locality, however, can be studied only by knowledge of local figures. Leaving the national data, let us look at the part played by tuberculosis in Newcastle-on-Tyne, an industrial city of 290,000 inhabitants, with a death-rate from tuberculosis in all ages about 50% greater than the national rate (1·03 per 1000 population in 1947).

TABLE V—DEATH-RATES FROM INFECTIOUS DISEASES (PER 100,000 LIVING UNDER 15 YEARS)

Year	Scarlet fever	Diphtheria	Whooping-cough	Measles	Anterior poliomyelitis	Tuberculosis
1939	15	228	140	34	10	237
1945	7	67	79	80	4	252

Table VI gives the total deaths and the four most important causes of death for the years 1939–47 inclusive, in age-groups 1–5 and 5–15. In the group 1–5, tuberculosis is second only to acute respiratory disease, and in the school years it is the most important single cause of death representing 26% of all deaths. Indeed, it can be seen that in 1939–47 tuberculosis was the greatest single cause of death in children of 1–15, causing 23·5% of all deaths among them. About one-tenth of all the deaths from tuberculosis in the city were at that age.

The great need for local study and assessment of the problem from year to year is emphasised by the contrast between the above figures and those published by

TABLE VI—DEATHS IN CHILDHOOD FROM TUBERCULOSIS AND OTHER CAUSES (NEWCASTLE-ON-TYNE, 1939–47 INCLUSIVE)

Age-group	Deaths in age-group (all causes)	Acute resp. dis. with measles and whooping-cough	Tuberculosis	Diphtheria	Violence
1–5 years	497	157	106	68	72
5–15 „	523	60	136	59	113
—	1020	217	242	127	185

clearly. Some paraplegics cannot manage the accurate positioning which is needed; these will mostly be cases combining tic douloureux with disseminated sclerosis.

Though it seldom happens, it is unsatisfactory when a large petrous-needle angle is found and has to be corrected by trial and error, with two or even more skin punctures. What is needed is a radiological method of preselecting the site of puncture which will make the angle zero. Work is being directed to this end with encouraging results.

WARNING

Radiology emphatically does not offer any substitute for the time-honoured and slowly learnt uses of touch and inference. Still less does it reduce the need for the precautions proper to all deep injections of drugs. These are: to use adequate landmarks; to move the needle slowly and without force; to aspirate; to inject the drug in innocuously small doses separated by pauses for observation; and, when in doubt, to stop.

SUMMARY

The theoretical advantages of combining alcoholic gasserian injection with radiology are obvious and long recognised. Previous attempts to combine them are here reviewed and criticised.

A new practical method has been devised on geometrical and radiological principles.

This method, with two simple projections and no screening, quickly locates the needle point in all three dimensions of space and in exact relation to the foramen ovale.

The positioning for these two projections is fully described; here Harris's guide lines find an additional sphere of usefulness.

An analysis of 135 consecutive attempted injections is made, and of these 66 unaided by radiology are compared with 57 aided by it. The results with radiology are decidedly better and still improving.

A warning is given against regarding radiology as an alternative to traditional skill and care.

I acknowledge my gratitude to my teacher, Dr. Wilfred Harris, for helpful criticism of this paper; to Dr. James Bull for two invaluable references to the literature, for tests of the rejected screening method, and for expert advice at all stages of the work, which owes its inception to him; to Dr. Douglas Gordon for experiments and guidance in positioning; to Mr. Wylie McKissock for constant interest and frequent encouragement; and to Miss Vivian Gee and Miss Susan Brown, past and present radiographers to the neurosurgical unit, St. George's Hospital, for their patience and accuracy.

THE MORTALITY OF
PRIMARY TUBERCULOSIS IN CHILDH

F. J. W. MILLER
M.D. Durh., M.R.C.P., D.C.H.
ASSOCIATE PHYSICIAN, CHILDREN'S DEPARTMENT,
VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE; LECTURE
PÆDIATRICS, UNIVERSITY OF DURHAM

RECENT writing demonstrates great differen opinion about tuberculosis as a cause of death illness in children. The papers of Moncrieff (1 Wilson (1947), Wallgren (1948), Gaisford (1946), Blacklock (1947), and the correspondence which fo them, make it clear that physicians who work i tuberculosis service and are responsible for the ca large numbers of adults think that pædiatri exaggerate the importance of tuberculosis, wh pædiatricians feel that the tuberculosis service whole gives insufficient attention to childhood infe and the toll which tuberculosis exacts from the c of this country.

A statement of the facts, so far as they are k may help to explain and reconcile the two views. data I shall chiefly use are taken from the Regi General's Statistical Review for 1945, and from annual reports of the medical officers of health Newcastle-on-Tyne from 1939 to 1947. My object show the present position rather than the historical

I shall consider children to the age of 15 years be that age usually limits the period studied by pædiatrician, though it does not limit the period primary infection with tuberculosis is important.

TABLE I—DEATHS FROM TUBERCULOSIS AT VARIOUS AG (ENGLAND AND WALES)

Age (years)	1936	1939	1942	194
0–1	359 (62·6)	319 (53·5)	339 (57·5)	307 (
1–5	1046 (42·7)	915 (43·0)	1058 (46·0)	1004 (
5–10	534 (17·9)	424 (14·9)	457 (16·6)	454 (
10–15	585 (17·7)	462 (15·2)	473 (16·2)	443 (
0–15	2524 (27·8)	2120 (23·7)	2327 (27·3)	2208 (
Deaths (all ages)	27,467 (67·3)	25,623 (62·1)	25,549 (65·7) (civilian)	23,464 ((ci

Figures in parentheses are the death-rates per 100,000 liv the age-group.

Under 15 years, tuberculous disease is almost al a result of primary infection producing patholo effects either by direct spread from the primary f by implication of lymph-glands, or by generalise intermittent hæmatogenous dissemination. Wheth not we call certain lesions post-primary is simp matter of terminology; and it is generally accepted clinical disease, if it occurs at all, is usually man within a year of the initial infection.

MORTALITY IN CHILDHOOD COMPARED WITH TOTAL MORTALITY

The tuberculosis mortality in England and Wal children in various age-groups, at 3-yearly inter 1936–45, is set out in table I, which also shows the number of deaths at all ages. It will be seen that i these years the mortality under the age of 15 repres rather less than 10% of the total mortality from disease—which may explain the view current in tuberculosis service that the problem presented childhood tuberculosis is relatively small. The figure parentheses represent the death-rates per 100,000 li population in each age-group, and it will be noticed t in the age-groups represented, there is a steady fall f almost 60 per 100,000 in the first year to 16 in age-group 10–15. It must be remembered, howe l mammary lymphatic chain, the anterior medias- was explored through the second or third inter- space in 50 consecutive cases. The material for gation from these cases always included a piece primary growth and tissues removed from the y of the internal mammary artery, and usually ole breast and axillary contents. Actual lymph- were recovered from the internal mammary chain patients. In 47 cases the intercostal space was ed immediately before or during a mastectomy, 3 cases when this was done as a preliminary ure it showed such heavy invasion of the space urgery was abandoned in favour of radiotherapy. eries is continuous in the practice of one of us . H.) except for the omission of those growths 8 in number) judged too advanced for any ion, and the addition of 4 unselected cases operated colleagues, where their indulgence and chance tted us to do an intercostal-space biopsy while were performing a radical mastectomy. The first es have already been published (Handley and ray 1947), but case 1 in that paper is omitted here se it was not in the consecutive series. All the ts were operated on during the past three years ut mortality. In 3 cases no axillary glands were ble for histological examination, and they were nted invaded on clinical grounds alone, but apart this all our findings are based on histological ce. For the purposes of the accompanying table those ry growths which it was difficult to assign to the or the outer half of the breast were arbitrarily lered to be in the inner half.

table shows that the internal mammary chain nvaded in 19 cases. In 16 of these the deposits in lymphatic glandular tissue, in 2 in the connective s adjoining the internal mammary artery, and in hin the lumen of a mediastinal venule. In 3 of 19 cases the internal mammary chain alone was ed, the axillary glands being free from growth; in 16 both axillary and internal mammary glands invaded. The axilla alone was invaded in 15 cases. landular deposits were found anywhere in 16 cases. tients with fairly large growths in the upper inner rant, in whom a frozen section of the second-space had given a negative result, had deposits in the space; but in general the routine was to explore second space only. It is remarkable that, of the rimary growths in the inner half of the breast h showed glandular deposits, 12 had metastasised e internal mammary chain and only 1 had invaded xillary glands alone.

e accident occurred in the series. A very short obese an was subjected to an apparently uneventful intercostal- biopsy. Towards the end of the radical mastectomy h followed there was great difficulty in maintaining her r. A needle was put into the pleura and, after the ation of much air, her condition greatly improved. It urprising to find it possible to wound the pleura without ccident being obvious, and more astonishing still to ver by radiography that the pneumothorax was bilateral. patient made an uninterrupted recovery from the tion after aspiration of the contralateral pneumothorax, ause of which remains obscure.

ATOMY OF INTERNAL MAMMARY LYMPHATIC CHAIN

ibbe (1918) is still the authority on this subject. internal mammary lymphatic chain is subject to variation. It lies deep to the plane of the costal ilages and is plexiform round the internal mammary d-vessels. Lymph-glands are usually present opposite first, second, third, and sixth intercostal spaces, second-space gland being the most constant. The n drains the anterior chest wall, breast, anterior iastinum, and (it is to be presumed) the upper rior abdominal wall and periphery of the diaphragm. It commonly empties itself into a gland situated just above the medial end of the clavicle, and thence into the great veins, but this gland may be absent. In addition to macroscopic nodes, there are in the internal mammary lymphatic network many tiny nodes, each composed of a few lymphoid follicles only.

LYMPHATIC SPREAD OF BREAST CANCER IN RELATION TO SITE OF PRIMARY GROWTH

Lymphatic involvement	Site of primary growth		Total
	Inner half of breast	Outer half of breast	
Total cases	17 cases	33 cases	50 cases
All lymph-glands free from growth	4 ,,	12 ,,	16 ,,
Internal mammary glands alone invaded	2 ,,	1 ,,	3 ,,
Axillary glands alone invaded ..	1 ,,	14 ,,	15 ,,
Both axillary and internal mammary glands invaded ..	10 ,,	6 ,,	16 ,,

SURGICAL REMOVAL OF INTERNAL MAMMARY LYMPH-NODES

To expose the internal mammary chain is easy. To find lymph-glands is difficult because they are often exceedingly small. The method of approach is as follows:

The chest wall having been exposed (either in the course of a radical mastectomy or by appropriate splitting of the pectoralis major muscle in the direction of its fibres) over the second or third intercostal space, an incision $1^{1}/_{4}$ inches long is made in the intercostal musculature, parallel to the costal cartilages and midway between them, and extending medially to the very edge of the sternum. This incision avoids injury to the perforating arteries, two in each space, which run forward in contact with the costal cartilages. The fibres of the intercostal musculature are cautiously divided with a knife until the mediastinal fat appears or the lung is seen through the pleura to be sliding to and fro. Sharp instruments are laid aside, and dissection proceeds with two fine non-toothed dissecting forceps and gauze. The internal mammary vessels are embedded in fibro-fatty tissue and lie about $^{1}/_{4}$ inch lateral to the edge of the sternum. They are picked clean, and a recognisable lymph-gland is often encountered, frequently in the superomedial angle of the space. All tissue removed deep to the internal intercostal muscle should be sectioned and will generally show unsuspected aggregations of lymphoid follicles. Oozing ceases with a temporary dry gauze pack, often within a minute, and definite bleeding can be checked with fine hæmostats. Wounding of the main internal mammary trunks is easy to avoid. A tear of the pleura, if recognised, is of no consequence when the anæsthetist has been forewarned of the possibility. The intercostal space cannot be closed after the exploration, since the intercostal muscles will not hold sutures.

DISCUSSION

The notes of the Middlesex Hospital cancer ward for 1806 record that a woman who died of cancer of the breast had deposits in the internal mammary lymph-glands at necropsy. The passage reads:

> "May 16, 1806. . . a married woman with offspring, aged 86, was admitted with a scirrhous breast and scirrhous gland in the axilla—the former commenced about 2 years ago, the latter a year since.
>
> Oct. 22. Opened. Near to the sternal end of the cartilage of the 2nd rib (internally) there was a scirrhous gland about the size of a small walnut. . . ."

About 1880 it became common knowledge, as shown by inspection of successive editions of *Gray's Anatomy*, that the inner part of the breast drained into the internal mammary glands. Little attention was paid by surgical pathologists to this knowledge, perhaps because surgical exploration of the anterior mediastinum held some risk before the advent of positive-pressure anæsthetic machines made a tear of the pleura hurtful only to the

Thompson (1947) from the Middlesex tuberculosis service—figures used by him to show that the problem of childhood tuberculosis is of no great importance and undoubtedly proving his point in so far as Ealing and Acton are concerned, but fallacious if applied to other areas (table VII). The difference in the number of deaths from tuberculosis in children of school age is particularly striking, and further data from other cities (table VIII) support the view that school-children in Newcastle-on-Tyne have an abnormally large chance of infection.

TABLE VII—DEATHS FROM TUBERCULOSIS (1942–45 INCLUSIVE)

Place	Population	Deaths from tuberculosis			
		All ages	0–5	–15	Total under 15
Ealing and Acton (Thompson 1947)	212,000	450	13	5	18
Newcastle-on-Tyne	270,000	1177	58	72	130

MORTALITY IN SPECIAL GROUPS

It has long been known that the mortality from tuberculosis is much higher in children of families containing an infective adult than it is in the child population as a whole, and the importance of intimate familial contact has been shown repeatedly—e.g., by Cox (1929), by Blacklock (1947), and by my own figures from the tuberculosis contact clinic for children under the age of 5 (Miller 1947).

In Newcastle the number of children under the age of 5 is 18,000, but in 1941–45 one-third of all the tuberculosis deaths below that age occurred in a small group of nearly 400 children belonging to households which contained an adult with notified active pulmonary tuberculosis. Of the 23 deaths in this group with family contact, 9 were in children who were tuberculin-negative when first examined in a "contact" clinic, and if effective separation had then been possible the deaths might have been prevented. *It is evident that the contact clinic, especially for the very young children, could be an important means of reducing deaths and morbidity of tuberculosis if it were supported by some effective method of separating young children from infection.*

The other fact which is generally accepted is that, in children up to 12, the younger the age of infection the greater the risk of a fatal outcome of the primary infection. This has been shown by many authors, and my own small series of figures in Newcastle prove its truth; and yet one is tempted to ask how often this knowledge has been applied.

CONCLUSION

I believe the facts presented here show the importance of tuberculosis as a cause of death in childhood, and emphasise that it must be controlled if as a nation we intend to reduce the death-rates of children. I have in this paper confined my attention to the mortality from tuberculosis in childhood; but I am, of course, only too conscious that other factual knowledge will be needed before the full significance of the disease in childhood can be appreciated. These facts, in England, have never been measured: we do not know the incidence of tuberculin sensitivity at different ages in variou the country or in different social groups; we statistics of morbidity from tuberculosis in ch and notification is certainly "a guide to the ascertainment rather than the incidence of in (Ministry of Health 1946). In Newcastle we are trying to compile information on these points studying the natural history of primary tuberc children in our own community; but we ca under any illusions. The only method of co tuberculosis in childhood is to prevent infection children are infected very largely from adu positive sputa. It is by the control of the adult that, ultimately, we must seek to protect

TABLE VIII—DEATHS FROM TUBERCULOSIS, UNDER 15 YEARS (1945–47 INCLUSIVE)

Place	Population	–1	–5	–15	Total under 15
City of Newcastle	290,000	8	27	44	79
Birmingham.. ..	1,076,000	26	85	57	168
Manchester	659,700	29	57	44	130

SUMMARY

The main purpose of this article is to sh tuberculosis appears so important to the pæ who is attempting to make childhood as free as from infective illness. Secondly, it demonst importance of local study to meet local needs.

1. In England and Wales in 1945 one-sevent deaths of children between 1 and 15 years we tuberculosis.
2. With violence and respiratory disease, tu is responsible for half the deaths between the 1 and 5 years.
3. At school age tuberculosis is the chief cause of death in England and Wales.

ASSISTANT PATHOLOGIST, MIDDLESEX HOSPIT

IT is well known that early cases of carcinom breast—the so-called stage-I cases—show a from recurrence of about 25% within five radical mastectomy. Since stage-I cases are *which the carcinoma is believed not to hav* beyond the breast, this result is inexplicabl the methods of deciding how far the malignan has advanced are less accurate than has been In deciding the extent to which carcinomat breast have extended, surgeons and pathologi concentrated their attention almost entirely one lymphatic exit for carcinoma cells from th of origin—i.e., the axillary lymphatic pathways

We show here that the internal mammary ly pathways are worthy of greater attention t hitherto been paid to them, and that in the least part of the explanation why radical mas in stage-I cases is not followed by 100% cure.

CKLY heat is exceedingly common among white e living in a hot climate, especially if the climate humid. It is usually considered a minor disability. he protracted discomfort it causes may seriously working efficiency and even health.

periments in a hot chamber at the U.S. Naval al Research Institute (Blum et al. 1945) were rned mainly in delimiting the climatic factor in etiology of prickly heat, and no record has been of any other controlled investigation under tropical tions. The experiment reported here was prompted e observation that an increase in intake of sodium ide was followed by severe prickly heat.

octor who had been free from prickly heat on the North n coast travelled to Karachi, India, by air, and at the time began to take extra salt because he felt he was now e in a truly tropical heat. Though the climate was bly no worse than the one to which he had been accus- l, he developed a very severe attack of prickly heat after days.

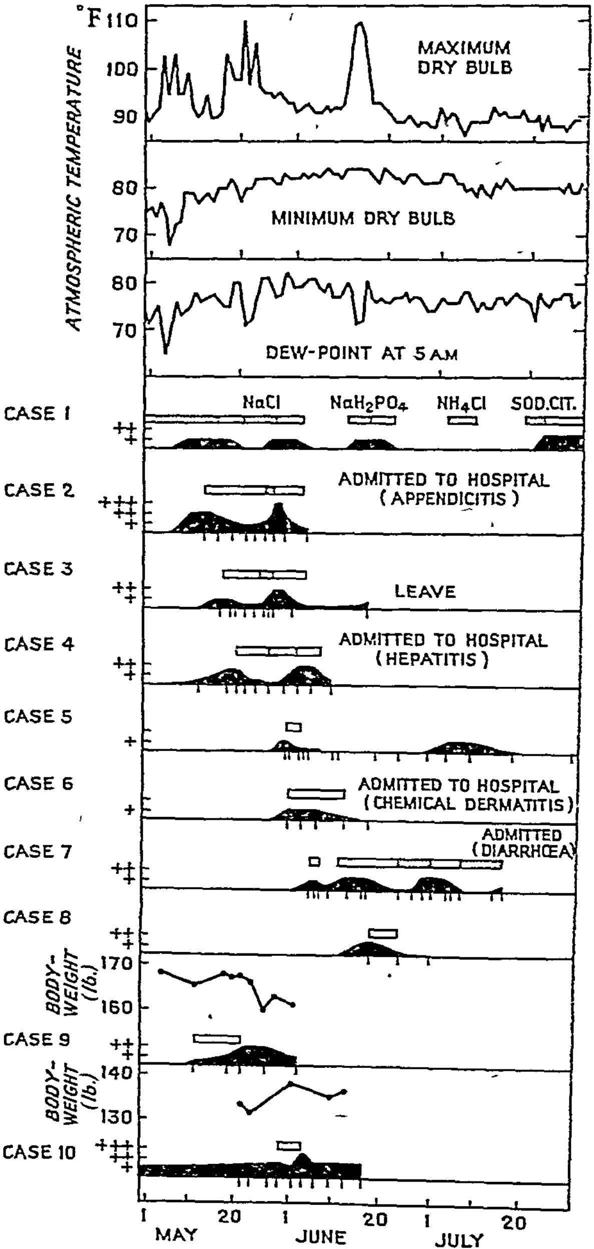
other doctor, whose duties were divided between Karachi, id place, and Cawnpore, a hotter but drier place, found t Cawnpore he was free from prickly heat and had to se his salt intake to avoid hypochloræmia, but that, on ing to Karachi by air, he developed prickly heat, which led only when he ceased taking the extra salt.

eral other similar histories agreed in incriminating lditional intake of sodium chloride as an ætiological in prickly heat, and in the late summer of 1946 al cases of prickly heat were treated by reducing intake and increasing water intake. The prickly of the treated patients improved, and of the ated controls remained stationary; but, since the her also improved at the same time, the result was clusive. In 1947 the investigation was repeated r in the summer, when the climate was, if anything, lily becoming hotter and damper.

METHOD

e subjects of the experiment were 10 members of the of the R.A.F. General Hospital, Karachi, who nued their usual duties during the whole period of nvestigation. They ate the normal staff food, which cooked with liberal additions of salt, but no addi- l daily prophylactic salt ration was taken. During ds of increased water intake the subjects ceased to salt to their food at table and drank 8–12 pints of r daily in addition to their usual fluid intake. king such large quantities of water was difficult, and liuresis inconvenient, but the investigation of 1946 suggested that an additional intake of at least 8 daily was necessary for an effect on prickly heat. inuous supervision of the water-drinking over al weeks was impossible, but coöperation was lly excellent. Selection of cases for the experiment ot influenced by the degree of coöperation expected. ng periods of increased salt intake fluid was reduced e normal habit in this respect and additional table aken. The quantity was not measured, but the salt added liberally to all meals and sometimes to ing-water. It is estimated that 10–15 g. daily was n in this way.

e subjects were examined at irregular but short vals, and on each occasion the severity of the ly heat was assessed. There seems to be no adequate al description of prickly heat, and this matter is too confused for discussion here. The most important features are the subjective sensation of prickling, which may occur even when the skin appears to be normal, and the objective erythema, which is distributed patchily and may be symptomless. Superficial epidermal vesicles are often but not invariably present. An arbitrary grading was adopted which took into account both the objective and subjective aspects, since discomfort in prickly heat may bear little relation to outward appearance. The days on which the men were examined are indicated in the accompanying figure, where severity is shown by the height of the black areas. Fluctuations reported as occurring between examinations are also shown.



Alterations in intensity of prickly heat produced by alterations in intake of water and salt. The intensity of prickly heat is indicated by the height of the black areas and the plus signs. Periods of increased water intake are shown by empty rectangles. The shaded rectangles indicate the periods of increased intake of sodium chloride, except where otherwise indicated (case 1). Weight records are given for cases 9 and 10 (see text). The vertical bars below each base-line indicate the days on which the experimental subject was examined (case 1, being one of the authors, is considered to have been under continuous observation).

ith an expenses grant from the Medical Research Council.

surgeon's pride. Halsted (1898) wrote of his intention to explore the internal mammary glands in cases of breast cancer but appears to have gone no further. Sampson Handley (1922) explored the anterior mediastinum in 6 cases and found lymph-glands in 2, both of which were invaded. In 1927 he published clinical evidence to show that the internal mammary glands were probably invaded at about the same time as the axilla, and he advocated the routine use of radium in the intercostal spaces as a prophylactic. Scarff and R. S. Handley (1938) suggested that the mortality from recurrence in stage-I cases after radical mastectomy might partly be explained by metastasis via the internal mammary chain, but that there was no microscopical evidence on this point.

The axillary glands have received voluminous attention in published reports and the internal mammary glands (which are a much more awkward problem) almost no mention whatever. Yet it seems clear that a carcinoma, when it is situated in the inner half of the breast, is likely to metastasise to the internal mammary lymphatic chain at the same time as, if not before, it has reached the axilla. When it is in the outer half of the breast, the axilla is likely to be invaded first, but this is followed, without much delay, by internal mammary metastasis, and patients who show extensive axillary deposits can be presumed, with considerable certainty, to have internal mammary deposits. These facts have hitherto neither been recognised nor accorded due weight.

To compare prognosis, results of treatment, and other matters in different series of patients, the system of staging cases of carcinoma of the breast has been widely used. Though at least five different methods of staging are in use, there are, very broadly speaking, three stages: (1) stage I comprises carcinomata still confined to the breast; (2) stage II comprises those which have spread beyond the breast but remain in its vicinity; and (3) stage III comprises those where more distant metastasis has taken place. Staging for scientific purposes is done on a combination of the clinical, histological and X-ray findings, and the point to which greatest attention has been paid is the histology of the axillary glands. The internal mammary lymphatic chain has been ignored. Yet when cancer cells have reached the internal mammary lymphatic chain they are inside the bony cage of the chest, separated from the pleura by only a millimetre or two, and safe from the radical mastectomist. The unfortunate patient showing such invasion harbours a carcinoma which has spread beyond the immediate vicinity of the breast and she must be assigned to stage III. If it is accepted that invasion of the internal mammary chain places a case of carcinoma of the breast in stage III, the effects of intercostal biopsy on the staging of the series of cases reported here is interesting. Without this evidence the cases would have been classified as 19 in stage I, 27 in stage II, and 4 in stage III. In actual fact there were 16 stage-I cases, 14 stage-II cases, and 20 stage-III cases.

Other indications have lately appeared that our knowledge of malignant dissemination has been insufficiently applied to the practical problems of breast cancer. Andreassen and Dahl-Iversen (1949) have shown that their method of "preventive" dissection of the supraclavicular region during radical mastectomies has yielded 17% of microscopically invaded supraclavicular glands. If the axilla has already been invaded, this figure has risen to 33%. If the axilla has not been invaded, the percentage is nil. They have concluded that, if the axilla is invaded, the supraclavicular region should be dissected at the same time as the axilla is cleared. But, if the internal mammary lymphatics are invaded as early as they seem to be, this recommendation of Andreassen and Dahl-Iversen would probably not make much difference to the ultimate result, and it is possible that some of the supraclavicular glands in Andreassen and Dahl-Iversen's cases may have been invaded internal mammary chain.

Saphir and Amromin (1948) examined serial of all the axillary glands from 30 cases of ca of the breast in which previous routine examinatio shown freedom from axillary glandular invasio growth; tumour cells were found in one or more in 10 of these cases ($33^{1}/_{3}\%$). Had the axillary internal mammary glands from our cases been sectioned, the number showing invasion might have been increased by a similar percentage, begins to look as though the number of cases in the growth is in actual fact confined to the b small.

One or two points are difficult to reconcile with importance which should attach to internal m invasion. It is, for example, uncommon to see recurrence at the anteromedial ends of the int spaces. Again, the actual deposits in the anterior tinum are small by comparison with those often in the axilla, and the largest invaded gland obtai the present series through an intercostal space small as a large orange pip. It might also be that primary growths in the inner half of the would be universally recognised as very much fatal than those in the outer half. Though some have found that this is so, others have thought the inner-half growths carried only a slightly prognosis. There is, however, no histological e to suggest that tissue defence against malignant in is more effective in the anterior mediastinum elsewhere, and the internal mammary lymphatic seems to be an adequate highway for the migratio carcinoma cells.

Exploration of the second intercostal space, as have described it, is not to be regarded as a metho treatment for carcinomatous deposits in the int mammary chain but as a reconnaisance designed to fuller information about the movements of the carci cells. The results obtained have indicated a pr in the treatment of carcinoma of the breast for no ready answer suggests itself. The only metho dealing with internal mammary deposits so far pub is Sampson Handley's (1927) technique of impla radium tubes in the medial end of the intercostal and its efficacy has not yet been unequivocally pr

SUMMARY

The state of the internal mammary chain has microscopically investigated in an unselected conse series of 50 cases of carcinoma of the breast.

In 19 cases deposits of carcinoma were found i internal mammary chain, in 3 of which the a glands had not been invaded.

The internal mammary chain is involved at the time as, or before, the axilla is invaded when the pri growth is in the inner half of the breast.

The technique of removing internal mammary ly nodes is described.

Our thanks are due to Mr. W. Sampson Handley D. H. Patey, and Mr. C. J. B. Murray for permissi operate on cases under their care and for their constr criticisms. Part of the expense of this investigatio defrayed by the British Empire Cancer Campaign.

RECURRING PNEUMOCOCCAL MENINGITIS

A. P. NORMAN
M.B.E., M.A., M.B. Camb., M.R.C.P., D.C.H.
RESIDENT ASSISTANT PHYSICIAN,
WESTMINSTER CHILDREN'S HOSPITAL

ECURRENCES of meningitis seem to be very unusual,
igh they may become commoner now that chemo-
apy has increased the chances of recovery from the
al attack. Most of the few published examples
e been pneumococcal. There are only two recorded
s, both in adults, of pneumococcal meningitis
rring without the presence of fracture or focal
ction (Arbeiter 1943, Craddock 1941). A third
aut 1945) in a child of 7 years may have been the
el of a fractured skull at the age of 4 years. Relapses
rring within a period of weeks are quite common
pelbaum 1945, Hopkins 1944, Craddock 1941,
idge 1940, Smith et al. 1946). In the case reported by
s (1947) a child aged 1 year 11 months recovered
n one attack of *H. influenzæ* meningitis and developed
ther attack eleven months later after an upper
piratory infection.

A case of recurrent meningitis in a woman aged 30
s recently seen at the Postgraduate Medical School
London (personal communication). Antral puncture
l bilateral Caldwell-Luc operations in 1942 were
owed by a foul discharge from the sinuses; in 1943
patient developed streptococcal meningitis and in
16 pneumococcal meningitis; in the third attack,
which she was admitted to Hammersmith Hospital
January, 1948, meningococci were cultured from the
ebrospinal fluid (C.S.F.) No meningococci or strepto-
ci were cultured from throat swabs on any of three
asions; X-ray films of the sinuses gave no definite
ormation: no evidence of cerebrospinal rhinorrhœa
uld be found in spite of a somewhat suggestive history.
covery followed treatment with sulphathiazole and
nicillin.

A boy aged 9 years was admitted to Oldchurch County
ospital (personal communication) in July, 1942,
neteen days after a fall followed by concussion;
ray examination of the skull had shown no bony
jury. He was found to have pneumococcal meningitis
hich responded to sulphapyridine. In March, 1943,
was struck on the left mastoid region by a stone,
d next day developed meningitis; pneumococci were found in the C.S.F. He recovered slowly but completely on treatment with sulphonamides and was still fit and well in 1948. In spite of the negative radiograph it seems likely that this child had had a fractured base of the skull: the relation of injury to the onset of meningitis is notable in both this and the first case described, but its significance as a cause of the recurrences is not obvious.

The response to treatment in the following case raises some important questions.

CASE-RECORD

A boy, aged 4½ years, fell on his head during March, 1945, but did not injure himself severely and did not lose consciousness; 2 days later he developed a headache with vomiting, drowsiness, and delirium, and on admission to hospital showed the classical signs of meningitis. The C.S.F. grew pneumococci type XIV on culture, and pneumococci were cultured from the throat swab. He developed a herpetic rash on the right side of neck and back and a partial 3rd (left) nerve palsy, but after a very stormy interval completely recovered. Treatment from the day of admission consisted of:

'Sulphamezathine' by mouth, 0·5 g. four-hourly for 8 days.
Penicillin intramuscularly, 4000 units four-hourly for 11 days.
Penicillin intrathecally, 8000 units daily for 10 days.
Pneumococcal antiserum intrathecally, on two occasions.

One morning in November, 1946, he was found comatose in bed, and on admission to hospital he had gross signs of meningitis. The C.S.F. yielded a pure growth of pneumococci, which were not typed; pneumococci were also isolated from the throat swab. He recovered completely in 3–4 days after treatment simultaneously with:

[illegible] three-hourly for 10 days.
[illegible] units four-hourly for 10 days.
[illegible] units daily for 10 days.

On the morning of Sept. 2, 1947, when he was aged 7, he fell on his head again, and again apparently did not hurt himself severely. However, at midday he had a severe frontal headache and by 3 P.M. was screaming with pain. He was brought into hospital unconscious and with signs of meningitis. The C.S.F. was under high pressure and looked milky; pneumococci type XXIII were isolated from it; pneumococci were also obtained from the nasopharynx, but were not typed. He was treated with:

[illegible] h, 0·5 g. four-hourly for 17 days.
[illegible] 40,000 units four-hourly for 33 days.
[illegible] rathecally, 40,000 units daily on Sept. 3, 4, and 6.

He rapidly improved and his temperature fell to normal, but on the 9th he relapsed and pneumococci were again present in the C.S.F. Therefore intrathecal injections of penicillin, 20,000 units daily, were given from Sept. 9 until Oct. 3. In spite of this he relapsed several times and pneumococci were grown from several specimens of C.S.F. On Oct. 4, a day after intramuscular and intrathecal penicillin had been stopped, symptoms recurred and pneumococci were found in the C.S.F. He was then given a highly soluble sulphonamide, 'Chemotherapeuticum,' * 1 g. four-hourly for 4 days and then 0·5 g. four-hourly for 7 days. He improved on this drug but again relapsed the day after the dose was reduced to 0·5 g.; a heavy growth of pneumococci was obtained from the C.S.F. on Oct. 11. He was given 10,000 units of penicillin intrathecally on Oct. 12 and 13; on the 13th 200,000 units were given intramuscularly six-hourly, and this was continued for 34 days. He had no further symptoms, and no pus or organisms were found again in the C.S.F. after Oct. 16.

The level of chemotherapeuticum in the C.S.F. was 5·7 mg. per 100 ml. while he was on the higher dose of 1 g. four-hourly, and 4·0 mg. per 100 ml. on 0·5 mg. four-hourly. The pneumococci were found to be fully sensitive to penicillin on several occasions in the course of the disease. The level of the penicillin in the C.S.F. inhibited the Oxford staphylococcus only at a dilution of 1 in 2 or 1 in 4. twenty-four hours after penicillin had been given intrathecally, on several occasions during the early part of treatment. He made an apparently complete recovery and is now normal physically and mentally.

All investigations directed to finding a focus of infection outside the meninges proved negative; numerous radiographs showed no evidence of a fractured skull, infection in mastoids

Salt as condiment, plus 8–30 g. daily	132	92	26	100

* Unpublished observations of D. T. Kay.

RESULTS

The initial effect of increasing water intake in persons with prickly heat was sometimes an increase in discomfort, but this passed off in a few hours. After two or three days a definite improvement was usually noted, and in 8 of the 10 persons the prickly heat was eventually much improved or completely relieved (see figure). Sometimes improvement was delayed for as long as ten days, and the impression was gained that the rate of improvement was proportional to the degree of coöperation obtained in drinking the large quantities of water prescribed.

In 5 persons the prickly heat was aggravated or brought on anew when an increased salt intake was substituted for an increased water intake. This deterioration was more rapid and more striking than the earlier improvement on increased fluid. In 2 persons (cases 2 and 3) it was necessary to cut short the second period of increased salt intake because of the excessive discomfort produced. In all 5 cases improvement with a high water intake was demonstrated on a second occasion.

The figure shows that the fluctuations in prickly heat did not always correspond with fluctuations in the environmental conditions. Some cases improved at the same time as others deteriorated. In fact all the investigations except those on cases 1 and 7 were completed during May and June, when the weather was slowly becoming hotter and damper. In spite of the notorious fickleness of prickly heat—its tendency to inexplicable spontaneous remissions and relapses—it seems clear that it was relieved by increasing water intake and aggravated by increasing salt intake.

Prickly heat was not produced de novo in 1946 or 1947 by a short period of very high salt intake—e.g., 100 g. in three days—even though other symptoms developed which could be attributed to salt retention. Once a person had already had prickly heat, smaller quantities of salt seemed to cause a relapse.

One of us (G. O. H., case 1), after twice producing prickly heat in himself with extra salt and relieving it with extra water, took in successive periods sodium dihydrogen phosphate (0·2 gramme-moles), ammonium chloride (0·8 gramme-moles), and sodium citrate (0·4 gramme-moles). Ammonium chloride was not followed by prickly heat, but each sodium salt produced prickly heat. In 1946 ingestion of sodium dihydrogen phosphate was followed by prickly heat in one of us (R. H. M.), who up till then had been free, but an increased water intake did not then relieve the prickly heat. Though the importance of the quantity of water needed was not then appreciated, it is interesting that the attack caused in case 1 by sodium citrate was not relieved by intensive water drinking for ten days.

An increased water intake failed to relieve spontaneous prickly heat in only two cases (9 and 10); in both of these there was a rapid deterioration. These were the
only two cases in which alteration in water
intake was associated with large fluctuations
weight. Observations recorded elsewhere sho
naturally occurring fluctuations in body-weigh
the hot season were greater in the people who d
spontaneous prickly heat than in those w
apparently immune.

OTHER OBSERVATIONS

Fay and Susman (1945), in a naval vessel in
waters, found that the incidence of prickly
60% in those taking a large additional ratio
(18 people), and only 25% in those taking no
or only a moderate amount (28 people).

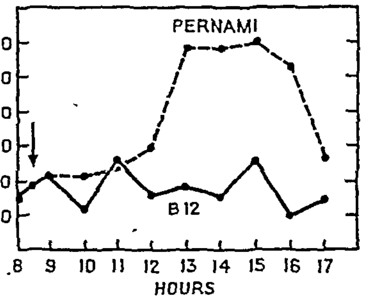
narrow into the peripheral blood, but this property st in the most highly purified extracts.

ras now of great interest to ascertain whether the crystalline anti-pernicious-anæmia factor * would iny effect on the leucocyte-count of normal people. ollowing experiment was therefore carried out in erworked nurse, aged 38, who had never been sly ill, and, in particular, had never had hepatitis. hite-cell count was followed for eight hours on two ssive days. On the third day an intramuscular ion of 40 µg. of the pure anti-anæmia factor was at 8 A.M., and the white-cell count was estimated g the first eight hours after injection. On the fourth 0 ml. of a potent liver extract ('Pernami' †) was injected intramuscularly and leucocyte-counts were made as before. The results are plotted in the figure, which shows that the crystalline anti-pernicious-anæmia factor had no effect on the leucocyte-count in this



tions in white-cell counts after intramuscular ction of 12 ml. of liver extract (pernami) and 0 µg of B_{12}.

aal person. One of us (J. D. unpublished) had found er that folic acid in doses of 25 mg. intramuscularly without effect on the leucocyte-count in normal ons.

DISCUSSION

either folic acid nor the crystalline anti-pernicious- mia factor has led to a final solution of the ætiology pathogenesis of pernicious anæmia. Ample evidence accumulated that there must be several factors not only a single substance the lack of which is onsible for all the hæmatological signs of pernicious mia. This is more likely in view of the elegant work arsen (1948), who, by a minute study of the diameter he erythrocytes, showed that in untreated pernicious mia both microcytes and megalocytes were increased, that after liver treatment the blood picture did not rn to normal but closely resembled that found in atitis and other forms of liver damage.

Whether the rise in the white-cell count usually erved in pernicious anæmia after injection of active r preparations is due to the factor found in crude r extracts causing leucocytosis in normal human jects and animals—e.g., sheep—or to the anti- nicious-anæmia factor itself is not yet known. The eriment reported here, clearly shows that the leucoosis factor of Dedichen, fractionated by Laland, is identical with the pure anti-pernicious-anæmia tor or with folic acid.

M. E. ROBERTS B.Sc. Lpool
BIOCHEMISTS AT THE HOSPITAL

It has previously been established (Harris et al. 1946) that the serum-cholesterol level depends on the capacity of the serum to hold cholesterol; the blood-fat and blood-protein levels are factors determining this capacity.

The present investigation was undertaken to ascertain whether the total fat content of the blood is raised in cases of high blood-pressure. While the investigation was in progress, we found that Wacker and Fahrig (1932) claimed that the blood-lipoid level is raised in hypertony, but their statement was based on only one or two cases. Peters and Man (1943) reported high blood-cholesterol levels in some cases of hypertony of renal origin, but said that in a group of cases of essential hypertony the blood-lipoid level was normal; they did not state the number of cases examined or whether they were established cases of hypertony. Poindexter and Bruger (1938) found a definite increase in cholesterol in arteriosclerotic and hypertonic patients, whereas Page and others (1936) reported that there was no increase in such cases.

It had already been proved conclusively that the increase in cholesterol is broadly proportionate to the increase in systolic pressure (Harris et al. 1946). In 46 outpatients the average age was 59, the average blood-pressure 180 mm. Hg, and the average serum-cholesterol level 216 mg. per 100 ml. In 20 patients whose average age was 60, but who had an average systolic pressure of 250 mm. Hg, the average serum-cholesterol level was 273 mg. per 100 ml. More striking still were the findings in inpatients. In 59 inpatients, whose average age was 55 and whose average systolic pressure was 188 mm. Hg, the average serum-cholesterol level was 208 mg. per 100 ml. In 27 inpatients whose average age was also 55, but whose average systolic blood-pressure was 241 mm. Hg, the serum-cholesterol level was 231 mg. per 100 ml.

INVESTIGATION

Total lipoid, total fat, phosphatide, and total cholesterol were determined in a series of patients with high blood-pressure and in others with normal pressures. The glucose-tolerance test was also applied in many cases.

Total lipoid was determined by Joseph's (1939) method: fatty acids by Bloor's (1943): total cholesterol by Ireland's (1941), as modified by him in our laboratory; and glucose-tolerance by that of Hagedorn and Jensen (1923). These determinations were all done with the patients fasting.

In the cases of high blood-pressure the systolic readings were 200 mm. Hg or more, and in the normal cases 140 mm. Hg or less. The great majority of cases of hypertony were apparently not of renal origin, but the series included a considerable number of patients who apparently had a postmenopausal hypertony.

The results were as follows:

	HIGH BLOOD-PRESSURE			NORMAL BLOOD-PRESSURE		
Substance	*No. of cases*	*Mean (mg. per 100 ml.)*	*Variance*	*No. of cases*	*Mean (mg. per 100 ml.)*	*Variance*
Cholesterol ..	35	268·2	163 3	50	178·2	28·7
Lipoid ..	35	982·6	1476·9	46	696·1	320·4
Fatty acid ..	37	625·8	607·8	21	420·4	629·6
Phosphatide ..	18	227 2	215·1	23	179·7	80·3

or sinuses, or any pulmonary lesion. at any time during 1945–47.

DISCUSSION

It is commonly accepted that meningitis may come about in one of the following ways:

1. (*a*) Direct extension from the nose in olfactory nerve sheath.
   (*b*) Via the lymphatics in purulent sinusitis.
   (*c*) Direct extension through bone.
2. Hæmatogenous spread from a focus in the nasopharynx or elsewhere.
3. Extension from the middle ear.
4. Extension through perforating wounds and fracture of the base of skull.

A possible cause of recurrences of meningitis might be the persistence of a small abscess in the meninges, following the first attack. Such a lesion has been noted at autopsy in a case of pneumococcal meningitis (Smith et al. 1946). This would certainly account for the obstinate tendency to relapse shown in the last attack of the case reported here. An abscess of this type might have formed in the period following the first, and inadequate, course of intrathecal penicillin, which was given for 3 days only; it might explain the failure to obtain a cure later with 24 successive days' treatment with intrathecal penicillin. The long-continued and intensive treatment with intramuscular penicillin may have eventually succeeded because the penicillin penetrated to the loculus through the blood-stream rather than the C.S.F. But such an abscess must be dismissed as a cause of recurrences in any of the cases mentioned, in view of the change in type of the pneumococcus which occurred in the present case and in the published ones; even a different organism was found in each of the three attacks in the Hammersmith case.

It seems necessary therefore to postulate in these cases either an abnormal path of entry for organisms between nasopharynx and meninges, or a periodic lowering of resistance which allows infection of the meninges to take place.

All writers on the subject emphasise the necessity for continuing the treatment long after apparent recovery in any case of pneumococcal meningitis. Appelbaum (1945) notes that the difficulty of treatment is probably due to persisting foci of infection. The case reported here again shows that intrathecal penicillin must be given for considerably longer than 3 days; it also illustrates the uselessness of giving high doses by that route, a procedure which may lead to fits, chemical meningitis, and other effects. The necessity for prolonging treatment is stressed by Smith et al. (1946) but the present case suggests that their dosage of intramuscular penicillin may sometimes be inadequate, a possibility implied in their own paper by the statement that relapses were common. It is likely that the final course of penicillin, solely intramuscular, was successful partly because of its duration but largely because of the high dosage. Bodian and Paterson (1946) have shown that the very low scale of 1000 units per lb. of body-weight per day is sufficient to control most infections, but there is a strong clinical impression that in rare cases many times this amount may be necessary; in the present example the daily dosage was 20,000 units per lb. of body-weight. This increased dosage may be needed when persistence or recurrence of infection is due to foci of infection situated in places, such as the meninges, which penicillin does not easily reach in sufficient concentration. It is reasonable to suppose that in the present case the concentration of penicillin in the blood-stream ultimately became high enough to penetrate to a pocket of infection which had been discharging intermittently into the subarachnoid space and was not accessible to penicillin in the C.S.F. It is, of course, still possible that the child will have a further recurrence.

SUMMARY

A child had three attacks of pneumococcal men at intervals of a year, of which the last attack extremely resistant to treatment.

The variation in the type of organism in th other known examples of recurrent meningitis s that infection enters each time from outside the me probably by extension from the nasopharynx.

The case emphasises the necessity of giving int penicillin for not less than five days in pneum meningitis.

Acknowledgment is due to Dr. B. W. Lacey and Dr. Stocker of Westminster Hospital bacteriology depart their work and helpful criticism; to Dr. Graham Bu his kind permission to quote the history of the case Hammersmith; and to Dr. E. Miles for permission to that from Oldchurch Hospital, and Dr. T. N. Nauth-M the details.

ANTI-PERNICIOUS-ANÆMIA FACTOR WHITE-CELL COUNT

JENS DEDICHEN
M.D.
CHIEF OF THE UNIVERSITY HOSPITAL MEDICAL OUTPA
DEPARTMENT

PER LALAND
CHIEF OF THE BIOCHEMICAL LABORATORY, NYEGAARD

OSLO, NORWAY

EARLY in 1948 Rickes et al. and almost simultan Lester Smith reported the isolation of the crystalline anti-pernicious-anæmia factor (named vi B_{12} by the American workers). The pure substan said to be active in pernicious-anæmia patient amounts of the order of 3–6 μg. Though the p which Laland and Klem described in 1936 was cl active only in doses as relatively large as 0·7 mg. the semi-crystalline and pinkish preparation mad Laland in 1939 in doses of 0·5 mg., astonishingly steps were necessary to achieve the final purification

Clinical trials with the pure substance by West (Spies et al. (1948), and Ungley (1948) showed th was able to restore the blood picture to normal and to combat combined degeneration of the spinal so far as can be judged from the few cases investi regarding this point.

Powers and Murphy (1933) showed that liver ex affected the white-cell count, pronounced leucoc appearing six hours after the injection of potent extract in normal persons. The leucocytosis essentially due to an increase in the neutrophil-c Laland (1939) and Dedichen (1939) showed that the to produce leucocytosis was associated with the anæmia principle through the process of purific up to one of the very last steps. The pinkish subs of Laland mentioned above, which was the preparation obtained before 1945, was devoid of leucocytotic action whatsoever, whereas this actio found in another fraction soluble in phenol-bu (20 : 80). This material (X PbPh) caused a di leucocytosis both in sheep and normal people in of 0·05 mg. (on a dry basis) per kg. of body-weight.

These experiments showed that crude liver ex contain a substance which, in minute quantities, a release of neutrophil polynuclear leucocytes fro

Reviews of Books

Textbook of Ophthalmology

Vol. IV. Sir STEWART DUKE-ELDER, M.D., D.SC. St. And., PH.D. Lond., F.R.C.S., director of research, Institute of Ophthalmology, University of London; ophthalmic surgeon, St. George's Hospital. London: Henry Kimpton. 1949. Pp. 1154. 70*s*.

THE first volume of Duke-Elder came out in 1932, and it was at once apparent that here was something out of the ordinary. The author's ability to arrange a mass of facts into an orderly and interesting tale was acclaimed everywhere, and we all wondered whether the standard would be maintained. That was 18 years ago and vol. IV has just appeared. During those 18 years a periodic masterpiece of medical writing has appeared from the author's hand and the present volume is no exception. Two more volumes are envisaged, and when the whole has been published we shall have a work of erudition and genius hardly paralleled in medical literature. This volume deals with the visual pathways, squint, errors of refraction, and clinical optical appliances. It opens with a warm tribute to Harvey Cushing, and the reader is then taken completely through the neurology of vision, with excellent illustrations from the works of Cushing, Cairns, Jefferson, and others. The remaining sections cover concomitant and non-comitant squint, ocular deviations and nystagmus, optical anomalies of the eye including aniseikonia, eye-strain, and visual hygiene, and lastly optical appliances.

Duke-Elder has become the standard reference book in ophthalmology in all languages, and rightly so. The present volume is as good as we expected it to be, and that is saying a great deal.

Sensory Integration

E. D. ADRIAN, O.M., M.D., F.R.C.P., F.R.S., professor of physiology in the University of Cambridge. Liverpool: University Press of Liverpool. 1949. Pp. 20. 1*s*.

MOST of Sherrington's work on which was based his book *The Integrative Action of the Nervous System* was done during his tenure of the Holt chair of physiology at Liverpool, and on the occasion of his ninetieth birthday the University of Liverpool instituted in his honour a Sherrington lectureship. The first lecture of the series is now published. In it Professor Adrian explains the rationale of Sherrington's study of the nervous system, and finds in the general principles he revealed the reason for his pre-eminence. So far as actual detail is concerned, technical advances in pharmacology, electrical recording, and the manipulation of nervous tissues have yielded a rich harvest of knowledge about the way the nervous system works, but much of it has little immediate bearing on the problem of integrated behaviour. In the field of sensory physiology, however, the new techniques can be applied to the study of the whole organism, and Professor Adrian goes on to discuss the implications of the discoveries he and others have made about the sensory patterns, in the form of nerve impulses, which pass from the periphery and have been shown to be reproduced in the cerebral cortex. However far we may be from understanding the connexion between brain and thought, the physical aspects of cortical activity are steadily being unfolded.

Geriatric Medicine

The Care of the Ageing and Aged. (2nd ed.) Editor: E. J. STIEGLITZ, M.D. Philadelphia and London: W. B. Saunders. 1949. Pp. 773. 60*s*.

THIS book, whose first edition appeared in 1943, is a departure from the past tradition of monographs on geriatrics. Nascher, Thewlis, Boas, Mueller-Deham, and Rabson all wrote with the personal experience of long years among elderly patients. Stieglitz has collected a team of 46 specialists whose contributions are bound together by the chapters which he himself writes. As might be expected, the geriatric inclination varies from writer to writer. The references are almost entirely American and little notice is taken of workers who happen to live in Europe. In consequence, certain chapters are lacking in orientation towards the problems

The differences between the means of the hypertonic and the normal groups were as follows :

Substance	*Difference*	*Standard error*	*Ratio*
Cholesterol	90·0	13·8	—
Lipoid	286·5	42·4	—
Fatty acid	205·4	35·2	—
Phosphatide	47·5	17·2	2·8

It will be seen that the differences for cholesterol, lipoid, and fatty acid are highly significant—i.e., there is little doubt that these substances are increased in cases of high blood-pressure. The difference for phosphatide is less marked ; but it seems likely that here also the amount is increased with high blood-pressure.

Age and Total Fat.—Blix (1926) has found that the serum-fat level does not increase with age though arteriosclerotic patches are more frequent in the higher age-groups. Our findings tend to support this finding. Tables I and II show that there is a definite relationship of total fat and cholesterol to hypertony, and not so much to the different age-groups.

TABLE I—SERUM-LIPOID LEVELS IN PATIENTS WITH HYPERTONY * AND IN CONTROLS † (NUMERALS IN PARENTHESES)

Total lipoid (mg. per 100 ml.)	Age-group (years)							Total	
	10–19	20–29	30–39	40–49	50–59	60–69	70–79	Hypertony	Controls
400	..	..	(1)	..	..	..	..	..	(1)
500	(3)	(2)	(1)	(2)	..	(1)	..	..	(9)
600	(2)	(4)	(3)	..	1	..	..	1	(9)
700	(5)	(3)	(4)	1 (1)	3	1	..	5	(13)
800	(1)	(3)	1 (3)	..	2 (4)	..	1	4	(11)
900	..	..	..	..	4	1	1	9	..
1000	..	..	..	1	3	1	1	5	..

1500	..	..	..	..	..	..	1	1	..
1600	..	..	..	..	..	1	..	1	..
Total cases	(11)	(12)	1 (12)	3 (3)	14 (4)	11 (1)	4	32	(43)
Mean level	.. (686)	.. (708)	850 (708)	983 (617)	914 (850)	1105 (550)	1100 ..	938 ..	.. (706)

* Blood-pressure 200 mm. Hg or more.
† Blood-pressure 140 mm. Hg or less.

Effect of High-fat Diet on Serum-cholesterol.—A high-fat low-carbohydrate diet raises the serum-cholesterol level. A high-fat diet was given for about three weeks, and after an interval of three days the patients were kept on a low-fat high-carbohydrate diet for about three weeks. In some cases we gave first a high-carbohydrate low-fat diet, followed by three weeks of high-fat low-carbohydrate diet. The averages of four serum-cholesterol levels read in the last eight days of the period were as follows :

Case no.	*Serum-cholesterol levels (mg. per 100 ml.)* *High-fat diet*	*Low-fat diet*
1	120	91
2	106	91
3	250	182
4	147	92
5	263	189
6	210	187

In cases 5 and 6 the low-fat diet was given for the first period and the high-fat diet for the second period.

Plotz (1949) suggests that a high-fat diet predisposes to coronary occlusion in patients who previously had had coronary disease. We should also like to draw attention to the fact that the way to lower the blood-cholesterol level is to lower the fat intake.

Effect of Insulin on Cholesterol and Fat.—Blood was taken from fasting patients before and at various times after the injection of insulin. It will be seen from table III that in each case the serum-fat serum-cholesterol levels fell.

TABLE II—SERUM-CHOLESTEROL LEVELS IN PATIENT HYPERTONY * AND IN CONTROLS † (. PARENTHESES)

Total cholesterol (mg. per 100 ml.)	Age-group (years)							T
	10–19	20–29	30–39	40–49	50–59	60–69	70–79	Hyper tony
100	(3)	(5)	(4)	(1)	..	..	..	.
150	(6)	(3)	(4)	1 (3)	2 (4)	2	..	5

Mean level	.. (175)	.. (171)	225 (183)	275 (163)	258 (192)	300 (278)	242 (325)	272 ..

* Blood-pressure 200 mm. Hg or more.
† Blood-pressure 140 mm. Hg or less.

Glucose-tolerance Tests.—Of 32 cases of high pressure, 23 showed abnormal curves—either the was higher than 170 mg. or the curve did not re normal fasting level within two hours. Three were on the borderline of abnormality, and only 6 gave a normal curve. Diabetes is a well-rec complication of high blood-pressure, but in all cases no sugar was found in the urine. Of 9 pe with normal blood-pressure whose glucose-tolerance tested, all gave normal curves.

COMMENTS

We have previously established (Harris et al. 1 that in cases of high blood-pressure there is a d retention of nitrogen ; but at that time we could no explanation for this observation.

The fact that carbohydrate as well as protein bolism is apparently abnormal in hypertony su that the anterior lobe of the pituitary gland, and merely the pancreas, is concerned in the abn glucose reaction. Overaction of the anterior lobe rise usually to symptoms which strikingly resemble of high blood-pressure—polyuria, decrease in tolerance, &c.—and it may ultimately be found endocrine disorders, particularly those affecting anterior lobe of the pituitary, may be one of causal factors, or the causal factor, in essential blood-pressure.

It is also known that the central nervous syste concerned with endocrine functions. It is inte that the frightening of cats (Lyons 1931) causes serum-cholesterol level to rise—an effect which ca abolished by sympathectomy.

TABLE III—EFFECT OF INSULIN ON SERUM-LIPOID

Blood taken with patient fasting before injection and at v intervals after injection, still fasting

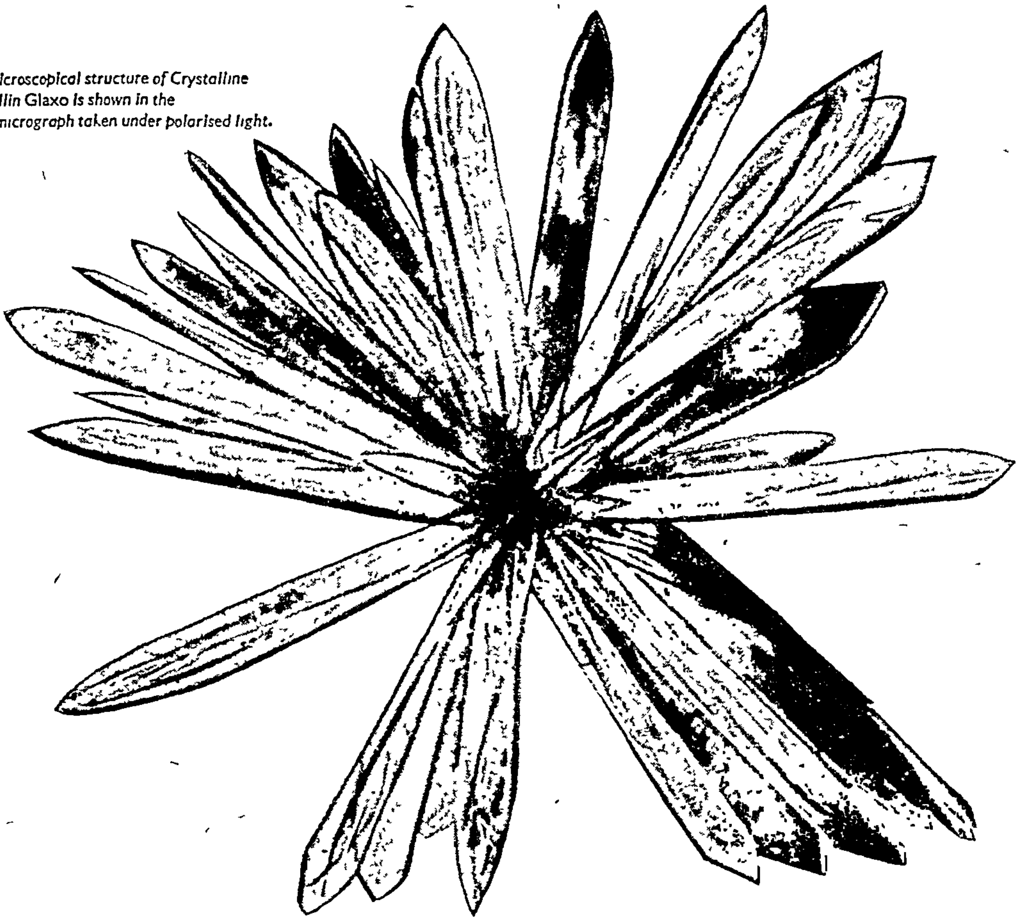
he microscopical structure of Crystalline
enicillin Glaxo *is shown in the*
hotomicrograph taken under polarised light.



CRYSTALLINE PENICILLIN G *Glaxo* contains over 95 per cent by weight penicillin G and has a potency not less than 1,600 units per milligram. It is exceptionally stable ; in the sealed container refrigerator storage is unnecessary. Apart from its special use in conditions where the purest form of the drug is essential, Crystalline Penicillin G *Glaxo* can also be employed for general purposes if preferred.

GLAXO

CRYSTALLINE PENICILLIN G *Glaxo*

In containers of 100,000 ; 200,000 , 500,000 , and 1,000,000 units

When an oil-wax suspension is required PROCAINE PENICILLIN G OILY INJECTION *Glaxo* offers significant advantages over earlier preparations of this type. Following a 1cc. injection, blood levels of penicillin are maintained for 24 hours in most cases. Very little deposition of particles occurs during storage and the preparation remains fluid at room temperatures. It can be readily withdrawn from the vial without warming. *In 10 cc. vials*

GLAXO LABORATORIES LIMITED, GREENFORD, MIDDLESEX.
BYRon 3434

of the elderly. For example, the management of a hemiplegic patient is dismissed in 28 words: occupational therapy only receives one short paragraph: and there is no specific mention of the problem of cor pulmonale.

Yet much of this book is above criticism. The first seven chapters contain an exposition of the basic foundations of geriatrics and gerontology which is unequalled. Everything that Stieglitz writes is profound, thoughtful, and stimulating. The chapter on coronary-artery syndromes presents several novel and interesting ideas. Other sections are competent summaries of existing knowledge in this field of medicine. The book contains a great deal of information which will be of the utmost value to those who have to diagnose and treat the diseases of elderly patients. It is well produced and clearly illustrated. If there had been reference to the progress made by workers like Himsworth, McMichael, Warren, Howell, and Cosin, it would be unquestionably the best book ever written on old age.

Methods of Psychology

Editor: T. G. ANDREWS. London: Chapman & Hall. 1948. Pp. 716. 30*s*.

IT is impossible to examine this collection without realising that psychology has ceased to be an arena for contending schools, and is now a serious science equipped with methods ingeniously appropriate to its varied subject matter. In his foreword Professor Andrews makes the salutary point that the facts and principles of psychology are always to be interpreted in terms of the methods used: though this is true of every science, it is particularly necessary to recall it in psychology, and to describe the diverse techniques and tricks by which investigators have brought into their subject exactness and order. The book is divided into twenty-two chapters, each written by an authority: E. G. Wever, for example, deals with the study of hearing, S. H. Bartley with vision, and P. T. Young with motivation, feeling, and emotion, while L. L. Thurstone returns to the methods of psychophysics, "a discipline which is fundamental to the problem of measurement in psychology"; he remarks further that the psychophysical methods transcend the older fields to which they have been applied and have become powerful tools in the solution of important problems in political and social behaviour. Statistical methods are the only ones omitted from this book: the reason is that, unlike the methods described here, they are fully dealt with in many textbooks. Although intended for students of psychology, the book has few chapters that are not of direct interest to the medical reader. The psychiatrist will turn chiefly to Saul Rosenzweig's section on the appraisal of personality, Joseph Zubin's on the objective study of disordered persons, Andrew Brown's on clinical techniques, and Helen Koch's on the study of young children; he will also find Theodore Newcomb's chapter on studying social behaviour profitable. Many of the chapters seem at first reading insufficiently detailed regarding the methods described: the book is not meant, however, for research-workers but for undergraduates, and every chapter has a bibliography reinforced by suggestions for further reading. As an authoritative review of a vast toolshop, describing lucidly the use of the various tools for the study of mental function, this is a most valuable compendium.

Lehrbuch der Embryologie

WALTER BRANDT, M.D., PH.D., lecturer in anatomy, medical school, Birmingham; formerly professor of anatomy, University of Cologne. Basle: Karger. 1949. Pp. 648. Sw. fr. 56.

THIS new German book on human embryology, which is clearly influenced by the work of Wolf-Heidegger, Kollmann, and Töndury, pays particular attention to experimental embryology. More than the first quarter of the book is devoted to general embryology, containing such features as a description of vertebrate gastrulation, the menstrual cycle and its endocrine control, and tests for pregnancy (the xenopus and ovarian hyperæmia tests, however, being omitted). The remainder of the book is concerned with systematic human embryology, the account of each system being preceded by a description of its developmental physiology. But, approximately a sixth of the book is occupied developmental physiology and experimental emb it is surprising to find no reference to the works of Reynolds, or Windle, or Barcroft's *Researches on P Life*. The emphasis on experimental embryology perhaps, overshadowed the sections on sys embryology, and there are occasional inaccuracies omissions in the latter. Thus the "crista div is described as the upper edge of the eustachian the circumvallate papillæ are reported as being the sulcus terminalis of the tongue, and no acc made of Van Dyke's and Klapper's recent work on fate of the ultimobranchial body. On the other the description of the development of the digestive is lucid and comprehensive. Improvements might made by mentioning the importance of the cortex in the ætiology of pseudohermaphroditism, describing the menstrual cycle *before* mentioning effect of the corpus luteum and progesterone on the metrium, and by adding a more detailed list of references given at the end of the book. This text of embryology, while emphasising the important tributions made to earlier embryology in Germany the application of the study of embryology to obst also embraces the progress made in America, as as in Europe, in the last twenty years, and for reason it will be particularly welcome on the Conti

Specs

BM/TTCE. Mem. Inst. P.R., F.A.D.O., Reg. Med St. Albans: W. Cartmel. 1949. Pp. 49. 3*s*. 6*d*.

THIS small booklet, which can be read from co to cover within the hour, gives all the essential d of spectacles. The general form of the book and chatty style make it easy to read, and it can be st recommended to all who wish for further informa about the kind of glasses they should wear or ab the glasses they are actually wearing. The author, prefers to remain anonymous, has for some years man a busy medical sight-testing centre and has acqu a sound knowledge of the sort of questions that peo wish answered. All the answers will be found in book.

Nelson's Loose-leaf Surgery: *Renewal Pages* (York: Nelson & Sons. 1949).—The latest renewal pages for book are concerned with burns, pigmented naevi and m mata, the lymphatics, vagotomy as a treatment for p ulcer, the rectum and anus, liver-function tests, the t urethral operation for prostatectomy, the operation of cystectomy, and the treatment of sterility, to which is ac an index. All these contributions bring the subjects up date, reach the high general standard to which we have accustomed, and will be welcomed by all who posses th useful work.

The Magistrate's Courts (Harmondsworth: Pelica Books. 1949. Pp. 222. 1*s*. 6*d*.).—Both for the layman wh shares the view that magistrates' courts are the place wh "they do the drunks," and for the magistrate himself, t book by Mr. F. T. Giles should be invaluable. Some membe of the bench have read Stone: others, who possess poo staying-power, would be well advised to read Mr. Gi The doctor, both as citizen and potential witness, can lea much from him: he contrives to be informative and entert ing. This is one of the Pelicans which many people w like to have bound in a less expendable form.

A Surgeon's World (London: Robert Hale. 19 Pp. 353. 12*s*. 6*d*.).—This book, by Prof. Max Thor is one of the now familiar success stories of Europ immigrants who have made outstanding medical careers i themselves in the United States. Like other works in t *genre* it combines the sentimental style of best-selling Ameri fiction with the inside life-and-death stories beloved of t general public; and, like them, it fails to tell us what be a surgeon is really like. It falls far short, for instance, of t great biography by Loyal Davis of a great predecessor Dr. Thorek's in Chicago, J. B. Murphy. We do, howev gain a vivid impression of the jungle of Chicago life in t early years of the century, and the author's thought concern for his juniors is clearly demonstrated.

THE LANCET

ONDON: SATURDAY, AUGUST 13, 1949

Counting our Blessings

ı the melancholy induced by recurrent dollar
and wet Bank Holidays, perhaps the contem-
n of death certificates is hardly the appropriate
iption: yet the Registrar-General's Review of
x years 1940–45 [1] contains much to interest and
en us. Certainly we can draw comfort from this
icle of the trends in the national mortality-rates
the critical war years; for at least some of the
icial effects of a war-time economy may still
from our peace-time austerity. The trans-
tic thirst for our best native brew may have
ved us of its solace, but the death-rates from
olism and cirrhosis of the liver have fallen
tly since early in the war. There has been,
a curious change in the age-sex specific death-
from degenerative heart-disease—a condition
ally attributed to excessive stress and strain.
een the wars the death-rate from this cause
rapidly increased; but during the late war
trend slowed down among younger men and
actually reversed among men of 65 and older,
among women of all ages—but particularly
een 35 and 50—there was a dramatic fall. No
convincing explanation can be given, but it is
nably supposed that the state of full employ-
, with the consequent relief from economic
eties, combined with the levelling effect of
ning on both undernutrition and overindulgence
minish cardiac strain. Again in diabetes mellitus,
ning may have had a beneficial effect. The
ial rations allowed to diabetics permitted a shrewd
nate of their number to be made on the basis of
claims reaching the Ministry of Food, and from
e it was deduced that some 4% of diabetic patients
from the disease during a year. But there were
ficant differences of specific age and sex groups.
oth sexes the mortality-rate notably diminished:
men it was 28%, and for women as a whole
, less than before the war. For young women
een the ages of 18 and 34, however, there was a
e increase in the diabetes death-rate during
-43 and a complete absence of any later improve-
t over the pre-war figure. Between the wars, it
ggested, young women were addicted to 'slim-
g" by taking inadequate meals—a cult which
t up their tuberculosis death-rate and diminished
r mortality from diabetes. Now, with better pay
canteen feeding, their diabetes death-rate has
eased, while at the same time, and presumably
the same reason, their mortality from anæmia
tuberculosis has decreased. Economic factors
lisease, it seems, cannot be ignored. Depression
ninating in suicide was at a peak during the
rs of economic hardship of 1931–35, and the
sequent fall in the frequency of suicide seems to
e accelerated in both sexes during the war. As
the Registrar-General suggests, a little cryptically, "fuller employment conduces to lower suicide frequency, even in groups whose work has become so hard as to cause continual complaint."

This seeming preoccupation with social factors should not be allowed to obscure the results of therapeutic innovation and sound preventive medicine, which are seen most strikingly among women and children. Maternal mortality continued to fall throughout the war, largely as the continuing result of the introduction of penicillin and the sulphonamides, blood-transfusion services, and better antenatal and postnatal care. The results of the antidiphtheria immunisation campaign are evident in the greatly reduced death-rate from this cause and in the much lower case-fatality rate among children thus protected, to which Sir **Wilson Jameson** draws attention in his 1947 report reviewed on p. 298. The diseases of infancy and childhood exacted a continuously decreasing toll, so that the death-rates among girls between 5 and 14, for example, fell by about 40% within a period of ten years, while the proportion of girl infants reaching their 5th birthday rose from 85% in 1910–12 to 95% in 1945.

Like previous ones, this Statistical Review is challenging because it raises at least as many questions as it answers. A survey of regional differences in mortality from exophthalmic goitre shows the existence of unexplained divergences in the death-rates in the country as opposed to the town: for example, the rates were higher in coastal areas than inland, and on the west coast and in Wales than in the rest of the country. During the past ten years, too, there has appeared a large and increasing male excess death-rate from leukæmia, and in neither leukæmia nor in the rapidly increasing death-rate from cancer of the lung do improvements in diagnosis provide a satisfactory explanation. In the regional differences in mortality—e.g., among infants in the first year of life and in respiratory tuberculosis—cause and effect may be more easily related, and some levelling of social or environmental conditions and perhaps of medical care is clearly indicated. Ominous signs of faulty hygiene, such as the present death-rate from diarrhœa and enteritis, must also be recognised; for the aim of this and succeeding Reviews will be served only "when the national conscience has at last been aroused by the persistent presentation of unpleasant statistical facts."

Prognosis in Disseminated Sclerosis

Disseminated sclerosis is a common disease in the British Isles; and yet there is little reliable information on its prognosis. Two valuable studies have recently been made in Scandinavia, by **Thygesen** [1] in Copenhagen and by **Müller** [2] in Stockholm, using different methods of case selection and follow-up.

Thygesen has taken all cases of disseminated sclerosis and acute disseminated encephalomyelitis admitted to the two largest neurological clinics in Copenhagen within a year of the onset of symptoms, and has re-examined them eight to fifteen years after their first admission; he has, however, excluded a previous retrobulbar neuritis as an initial symptom of the disease. His criteria for the diagnosis of

in the English language. In this country have, perhaps characteristically. been content ass our National Health Service Act without ing to inquire into such abstract matters.

om Boston, however. has lately come a small ne,[1] containing contributions by eight members e medical staff of the Massachusetts General ital and of the Harvard Medical School, which apts to grapple with some of the issues in terms ligible to the lay public: and the first essay. e development of the hospital. by Dr. EDWARD D. CHILL, is a thoughtful survey of the history of itals. Opening with a quotation from PLATO:

> hen must we not maintain that Asclepius . . . would attempt to protract a miserable existence by a ed regimen . . . thinking medical treatment ill wed on one who could not live in his regular round uties . . ."

CHURCHILL sharply comments that no hospital existed with the simple and logical mission ribed by PLATO: "Sickness is a matter of alarm, of logic." He writes with a mind wide awake he challenge now presented by the utilitarian roach. "It is of more than passing interest." writes, "to learn that in England. where the war need for industrial production is urgent and our is in short supply, a logical concept of the pital function in industry has appeared in a few ters such as Birmingham," whereas in America far neither management nor labour has grasped full utilitarian potential of the hospital as an uvant to keeping the wheels turning in the ustrial assembly line." Passing from a survey he hospital as an expression of the Christian virtues the relationship of the hospital and the medical fession. he writes:

> "This blending of the interest of the doctor with he function of the hospital led to a sense of responsiility and ownership. . . . Society. in turn. has been nly too ready to relinquish some of its responsibility nd relax its efforts. The doctors are supposed o know what they are doing, and comfort is taken in he attitude that it is impossible for a mere layman o judge of such matters."

his situation." comments Dr. CHURCHILL

> 'has created a disturbing undercurrent of thought hat only a few observers appear to notice. Is it well for society. or in the long run. for the profession that this trend continue? Can a not disinterested profession be entrusted with an agency of society that is becoming more vital today than ever before in history? However sincere the efforts of the doctor to provide the best of care for his patients. the fact must be faced that these same efforts provide him with the prestige and comfortable living which he claims. It is possible that the profession is unconsciously drifting into a dangerous position not wholly unlike that in which the Church found itself before the Reformation. If one listens carefully. a faint ringing of bells can be heard when some miracle of medical science is recorded in solemn protocol: salvation in this world can be achieved only if you 'consult your doctor.' and the pain and anguish of the fires of hell will overtake the ignorant or wilful who fail to heed this admonition. The quest for individual survival in this world is fully as intense as the older hope for personal immortality in the next."

It is difficult, he recognises. to place the hospital gainst the background of social and economic history without risking false interpretations and conclusions: but if the forms taken by the hospital in the course of history are left standing only against the background formed by changing modes of expression of the Christian virtues and the progress of medical science, the impression created is unrealistic and incomplete. From such a setting Dr. CHURCHILL approaches the voluntary hospital of the eighteenth century in England:

> "It was not an outgrowth of experience with the great social and economic changes that were brought by the machine age. but a pre-formed pattern that has struggled valiantly during the nineteenth and nearly half the twentieth century to meet needs and cope with problems that were unknown at the time of its origin. With all its shortcomings and inadequacies. it has performed a mighty service by maintaining standards of ethical purpose and humanitarian ideals during a period of changing values. The blending of these attributes with the scientific medicine that developed so swiftly in the last half of the nineteenth century has established the pattern of Anglo-American medicine for the present century."

Reflection on what might have happened points a moral for our own day:

> "As a contrast it is of interest to consider what the course of medicine might have been if set by the government of England at this time. During the eighteenth century in England the government went on adding statute after statute to the "bloody code" of English law. enlarging perpetually the long list of offences punishable by death; finally they numbered two hundred.' This was the period of iron discipline and cruelty in the Royal Navy and the Army. Any form of the hospital cast in the mold of the state of that century might well have blighted the growth of the medicine that was to come. or warped it with the impersonal and arrogant qualities that were recognizable in the medicine of Germany. But the hospital in England was formed by society acting independently of the state and it was this pattern that was transferred to the Colonies that have become the United States."

When he comes to deal with the hospitals in contemporary society. Dr. CHURCHILL wisely refrains from dogmatism. He is refreshingly free from the bias which to many of us in Britain today seems to characterise most American reflection upon the great social experiment now in progress here. His treatment of the subject becomes hesitant and thoughtful: and well it may. After noting that "those responsible for the future of our social institutions are searching for frames of reference that distinguish essential functions from what may be organizational fetishes" he returns again to the temptation to regard the hospital solely as a utility. The care of the sick in hospitals is a far more complicated matter than providing utilitarian technical service.

> "The hospital is one of the most complex and dynamic instruments of contemporary society. It is an interface where the logical concepts of science have made contact with those powerful nonlogical actions of man that center in his survival and release from the fear of suffering."

It is tempting to go on quoting, but this is perhaps enough to show the quality of Dr. CHURCHILL's essay. Dr. NATHANIEL W. FAXON, who has edited the volume and written a final and useful summary of the present situation in the United States. is to be congratulated on his achievement in bringing together a group of men able to think seriously about issues that have been strangely neglected.

The Hospital in Contemporary Life. Eight essays by members of the staff of the Massachusetts General Hospital. Editor: NATHANIEL W. FAXON, M.D. London: Oxford University Press. 1949. Pp. 288. 27s. 6d.

disseminated sclerosis were: (1) neurological symptoms, especially those referable to the pyramidal tracts, in a patient in whom retrobulbar neuritis had previously occurred or was simultaneously present;. (2) remitting symptoms due to lesions of the pyramidal tracts, including tracts mediating sphincter control, when no other cause could be found; (3) remitting paræsthesiæ when no other cause could be found; (4) symptoms referable to the pyramidal tracts, regardless of earlier symptoms of retrobulbar neuritis or the remitting or non-remitting character of the symptoms, when no other cause could be found; and (5) monosymptomatic forms which could be shown not to be due to syphilis or arteriosclerosis and were not associated with notable changes in the cerebrospinal fluid. He admits that the exact status of acute disseminated encephalomyelitis is uncertain, but this diagnosis was made in cases where there was an immediately preceding infection, pyrexia, an acute onset with rapid progress of symptoms, or prominent encephalitic symptoms. Initially there were 84 cases of disseminated sclerosis, 29 of acute disseminated encephalomyelitis, and 31 in which disseminated sclerosis was tentatively diagnosed. At the follow-up it was found that 5 of the cases of acute disseminated encephalomyelitis had died (4 within a year of the acute illness), 13 remained free of neurological symptoms, 7 had developed into typical disseminated sclerosis, and 4 were later considered to have encephalitis lethargica. Of the 31 cases with a tentative diagnosis, 19 were later considered to be suffering from disseminated sclerosis. This elimination of cases left 110 with a firm diagnosis of disseminated sclerosis for consideration. Within fifteen years of the onset of symptoms a third of these patients had died. A quarter of the cases had run a benign course, 13% of them being completely or practically free of symptoms after eight to fifteen years, while in 12% there had been long remissions or the disease had *become stationary at an early age so that the patients* were able to work at the time of the follow-up examination. The remainder of the patients were moderately or severely disabled. Some information on the ultimate prognosis could be deduced from the course of the disease in the first year or two. In general the disease ran a relatively benign course when the onset had been acute or subacute and when there had been a total or partial remission during the first year: in practically all the cases with an insidious onset and steady progression during the first year the subsequent course was unfavourable. Changes in the cerebrospinal fluid were of no value in assessing the prognosis. On the whole, the course of the disease was more benign in the higher age-groups.

Müller has studied a considerably larger series of 810 patients, in whom the diagnostic criteria seem to have been strict. The case material was obtained in a different way; patients in whom the diagnosis was made in two hospitals in Stockholm and one in Uppsala during 1920–45 were re-examined in 1946, or when the patients had died the relatives were interviewed. Of these 810 patients, 63% had a history of more than ten years from the onset and 22% of more than twenty years. At the time of the follow-up 190 patients (23·5%) had died, the great majority of urinary or respiratory infections or toxæmia from bed-sores; in 19 cases the cause of death appears to have been unrelated to the neurological di 6% of the patients had died within five years initial symptoms and 34% within twenty Two-thirds of the patients in whom the obse period was at least fifteen years had become in within this period. **Müller** found that whe initial symptoms were cranial-nerve or sensory turbances the outlook for remissions and a rel benign course was decidedly better than disturbances of motility or of sphincter occurred early. On their first appearance nerve and sensory disturbances cleared up in quarters of the cases, motor disturbances in a and sphincter disorders in only an eighth. W the initial symptom, if it persisted for six mo complete remission was unlikely. When disse sclerosis first appeared in older age-groups a progressive course without notable remissions much more probable than the remitting type of disease common in younger people.

These studies give a valuable general pic the natural history of disseminated sclerosis; but prognosis in an individual patient remains rem difficult. The most that can be said is that c rapid onset, patients with initial cranial-nerve sensory disturbances, and those in the y age-groups are likely to have remissions of the When the disease has a slowly progressive which is the commoner type in the older remissions are unlikely. In the early stages important not to take too gloomy a view, since 25% of **Thygesen**'s patients there was rela little disability eight to fifteen years after the of symptoms, excluding retrobulbar neuritis is a general impression that pregnancy and partu may precipitate relapses of disseminated sclerosis aggravate existing symptoms, but in his mat **Muller** found no evidence to support this idea.

Towards a Philosophy of the Hospital

What one might call the philosophy of h provision has been taken very much for gr The hospital in history has been unaccoun neglected by social historians, and medical his have too often been content with a few brief refe to the hospitals of antiquity and of m Christendom. But now that planning—and p to a large extent from the centre—has become but a necessity, it no longer suffices to go on in matter-of-fact way. A sense of background and idea of the direction in which we are movi indispensable. It may well come as something a shock to realise that three different ideas of purpose of a hospital are current, and that the signposts point to paths that are far from conv on the same destination. The first, and still do idea, is that the hospital exists for the relief of suff the second is that the hospital exists to assist doctor in the preservation, or maybe prolonga of human life; and the third, which is gaining today, is that the hospital exists for the good of community, understood in a sense that would of cuts in the hospital services if it could be shown resources of man-power or money could be " profitably " used in preventive medicine. The large and difficult questions with an obvious pra bearing; yet we know of no reasoned discuss r to that of streptomycin. Clinical trials with it een made by continental workers. According to rps and Kalkoff[6] it produced clinical improve in 80% of patients with lupus vulgaris. Equally aging are the reports of its effect in intestinal ulosis and tuberculosis of bladder and of bone.[7] 98 is apparently effective in early exudative cases monary tuberculosis,[8] but not in miliary tuber ; or tuberculous meningitis. The drug appears to newhat toxic. since it may cause vomiting, albu ia, jaundice, and cerebral œdema. These reports be accepted with reserve, for the investigations have een submitted to such rigid statistical control as cent M.R.C. trials with streptomycin.[9] Evaluation accumulation of individual clinical experiences variety of types of tuberculosis takes a considerable and the conclusions, being based on clinical ssion, are far less reliable than those formed by a of investigators whose individual reports are sed by an experienced medical statistician.

A RACKET IN NURSING

E opinions expressed in our leading article of 30 on the Dangers of Uniformity had no reference e Ministry of Health's circular, dated July 27. dding the engagement of nurses at more than the lard rates.[10] In this case the Ministry have excellent ns for the action they have taken; for the circular signed to end a long-standing abuse. A coöperation nised to hire out private nurses for genuinely private is one thing; but when hospital nurses resign hospital work, join the coöperation, and are then l back to the hospitals at a fee considerably higher the salary they were receiving from the hospital; when moreover they thereby set themselves free hospital discipline by an attitude to authority h may be summarised as "Very well then. I shall it is obvious that something must be done. This is a new practice; already before the war it was causing ous trouble in London hospitals. In a report as long as June. 1938. the Voluntary Hospitals Committee London said:

> "Many of the private coöperations appear to have tgrown their original function (supplying of nurses for mporary private work either in the patient's own home, nursing-home. or private ward in hospital) and advertise r nurses to take general duties in hospitals. They have rge numbers (in one case, several hundreds) on their oks engaged solely in general duties in hospitals. Such rses are employed to supplement the permanent hospital affs at salaries of £2 2s. or £3 3s. per week. plus residence. ome years ago a few of the 'special' and smaller hospitals, xperiencing difficulty in keeping their staffs at full strength. mployed a small number of nurses from private coöpera ions in emergency and during holiday periods, but recently he practice has grown and new agencies have sprung up. ften on a 10% or 15% commission basis, so that now undreds of nurses, attracted by the higher remuneration nd greater freedom from restraint, join the private coöpera ions expressly for hospital duties. Many of the permanent taff become dissatisfied and unsettled. feeling it an injustice hat temporary staff performing exactly the same duties hould be getting in some cases more than double their alary, while free to terminate their engagement at any ime by giving twenty-four hours' notice. Moreover, the onstant changes in the staff make it extremely difficult to naintain a good tone or high standard in the hospitals."

With a shortage of nurses, and disparity between the tes paid in hospital and the rates demanded and tained for nurses hired out by the coöperations. it s naturally been difficult for authority to intervene. reaching its decision to do so the Ministry has had to strike a balance between, on the one hand, the embarrassment that will be caused to hospitals still desperately short of staff. which have come to regard the employment of "private" nurses as a regrettable necessity, and, on the other hand, the probability that a good many nurses will return to hospital work under conditions decidedly more satisfactory to the hospitals. Taking into account the improvement in the rates of recruitment of nurses to hospital work, and the somewhat increased rates of pay, the Ministry has decided that the racket should now be ended.

THE HYGE B.C.G. STATISTICS

Dr. Tage V. Hyge's schoolgirls in Denmark promise to become as famous in the history of B.C.G. vaccination as Dr. Heimbeck's nurses at the Ullevaal Hospital in Norway. In both cases several of the requirements of an experimental investigation are fulfilled, and in both cases follow-up studies are being pursued. It will be remembered that Hyge's schoolgirls. numbering several hundreds, belonged to a large school in Copenhagen where the story began in October, 1941, with the discovery of a case of cavernous pulmonary tuberculosis in a girl of 15. This discovery led to systematic tuberculin and other investigations of the scholars and their teachers. Early in 1943 there was an almost explosive. influenza-like. outbreak of tuberculosis in the school, and the source of the infection was found to be a teacher. The children were classed according to whether they were originally tuberculin-positive or tuberculin-negative, the latter being put in two groups according to whether they were or were not vaccinated with B.C.G. Like Heimbeck. Hyge found a low tuberculosis-rate among the originally tuberculin-positive girls, and among those who. originally tuberculin-negative, were vaccinated with B.C.G. On the other hand. the tuberculosis-rate was very high among the originally tuberculin-negative who were not vaccinated with B.C.G.

From time to time Hyge has published further observations, and now, after an observation period of five years, he brings his figures up to date.[1] Of the 94 originally tuberculin-negative girls exposed to infection and not vaccinated with B.C.G., 70 became tuberculin-positive. and 41 of them showed definite signs of tuberculosis. Of the 106 originally tuberculin-negative girls exposed to infection and vaccinated with B.C.G., only 2 developed pulmonary tuberculosis. Of the 105 originally tuberculin-positive girls exposed to infection, 4 developed pulmonary tuberculosis. Hyge concludes: "We ought therefore to vaccinate with B.C.G. all who are tuberculin-negative."

REMOVAL OF THE AURICULAR APPENDIX FOR EMBOLISM

PERIPHERAL arterial embolism is a common complication of mitral stenosis. and in over 90% of such cases the emboli arise in a thrombus attached to the wall of the left auricle, or more usually its appendix. The arterial embolus can be successfully removed, but recurrence is common because the auricular mural thrombus remains. and recurrent embolism is often fatal because the cerebral arteries are apt to be involved. The only radical cure lies in removal of the thrombus.

American workers[2] have shown that in dogs it is feasible to resect the appendix of the auricle and that the scar in a short time has a complete internal covering of endothelium. Following this approach Madden[3] has operated on two patients. The first. a woman of 38, had had an embolism of the left common iliac artery. treated by embolectomy, in 1946. Over a year later the right popliteal artery was similarly affected and success-

Annotations

SICKNESS AND THE N.H.S.

THE routine collection of statistics can be justified only by their usefulness either in research or in administration. In this last respect at least, the work of the Social Survey [1] on behalf of the Ministry of Health is now paying its first dividends. In the heated discussions inevitable during the birth of a new health service, some cold facts may have a sedative effect.

Since 1944 the lay interviewers of Social Survey have been visiting the homes of a small randomly selected sample of the adult population of England and Wales. Those interviewed are asked about their sickness experience in the previous three months, the incapacity thus caused, and the frequency of consultation with the family doctor; and at the same time information is collected about age, sex, and economic status, so that incidence, prevalence, and incapacity rates can be worked out for the corresponding groups of the population. Similar surveys were conducted during the second six months of 1946, 1947, and 1948, and these permit comparison of the estimated frequency of illness and the calls made on general practitioners during the three periods, before and after the coming of the National Health Service. Some criticism has been levelled at this type of morbidity survey; but, so far as these simple measures are concerned, their consistency over the months suggests that their evidence is reliable. For want of better, these results can be our present guide.

The monthly sickness-incidence rates—i.e., the numbers of *persons* reporting some illness or injury during the month per hundred people interviewed—were in 1948 almost the same as in the corresponding periods of 1946 and 1947. Closely related to these are the prevalence-rates based on the numbers of *sicknesses* or *injuries* suffered by those interviewed, and, as expected, they show little real difference in prevalence in the three periods. On the other hand, incapacity-rates, which derive from the numbers of days away from work, or (among those not employed) the number of days confined indoors, did show some significant trends. For example, among elderly women (aged 65 and over), the incapacity-rate in 1948 reached the record level of 430 days lost per month by each hundred women interviewed. In general there was in 1948 an increase in the incapacity-rates of some 25% over the previous years, largely because of greater losses among women and people over 65. At least some of this increase in incapacity among older people may result from a caution advised by their doctors, whom they consulted much more frequently in 1948 under the new régime. Though the consultation-rates for men between 16 and 64 changed little, women—particularly the older ones—saw their doctors with a frequency greater by 10–26% than before.

A long overdue interest in the welfare of housewives has prompted some comparisons between their sickness experience and that of other women. Direct comparisons are obscured by age differences; but, though housewives do appear to report more frequent illness, they have fewer days of incapacity and consult their doctors no more often than do their sisters. Perhaps this might have been anticipated: when a housewife is also a mother she can seldom afford the luxury of incapacity in the sense used here.

Some tentative suggestions are made that there has been an increase in the consultation-rates among the poor of both sexes, and—a little oddly—among better-off men; but the evidence of this is still insecurely based. Enough has been demonstrated in this report, however, to quieten the wilder statements about our national deterioration, and at the same time to justify the of general practitioners that the new service has in the demands on them. No doubt this increase w still more obvious if children were included in the

It may be of interest to mention here the Gov Actuary's statement [2] that since the middle of there has been a gradual downward trend in the short-term illness, which had risen during the war. figures, he concludes, "suggest broadly that in aggregate the pre-war level of short-term inca had been regained prior to the introduction of the comprehensive scheme of National Insurance in 1948."

NEOMYCIN AND TB1-698: TWO TUBERCULOCIDAL DRUGS

STREPTOMYCIN has two serious drawbacks as a therapeutic agent in tuberculosis—its neurotoxicity the relative ease with which the tubercle bacillus acquire a resistance to it. It was hoped that these be overcome by the use of dihydrostreptomycin. although this derivative is less toxic than the substance, it produces resistance in the bacillus. sulphones and *p*-aminosalicylic acid, though useful, less effective than streptomycin. So we must still tuberculosis as a killing disease for which a fully factory remedy remains to be discovered. Perhaps n has been more aware of the limitations of strepto than Waksman, its discoverer. With his team at R University, New Jersey, he has, during the last years, isolated many thousands of cultures, actinomycetes belonging to the genus *Streptomyces*, soils, composts, peats, and other natural substrates, the hope of finding a non-toxic antibiotic effective the tubercle bacillus yet not producing resistance protracted administration. These investigations resulted in the discovery [3] of a new antibiotic, n neomycin by Waksman, which appears to satisfy t criteria. The organism producing neomycin was ob from the soil and is related to a culture isolated as back as 1915 by Waksman and Curtis and design as *Streptomyces fradiæ* (*Actinomyces fradii*). The an biotic can easily be removed from the culture med in which it is grown and concentrated by the method adsorption and elution that have been developed for isolation of streptothricin and streptomycin. It i basic compound, soluble in water, thermostable, active against numerous gram-positive and gra negative bacteria, especially mycobacteria. The an biotic has not yet been obtained in crystalline form and very little is known of its chemical nature. In-vivo tests and observations with hens' eggs and mice have shown that neomycin is as active against streptomycin resistant as against streptomycin-sensitive strains tubercle bacilli, and that it is more active than strept mycin against some strains of *M. tuberculosis*. Neomyc has a relatively low toxicity and so far, apparently, h not produced resistance in organisms sensitive to it. Th results are indeed promising: but its true value cann be assessed until there is enough of the antibiotic f clinical trials.

With the sulphonamides as starting-point, Domagk and his collaborators in Germany attempted to prep a new series of tuberculocidal drugs derived from sem carbazide. The most effective appeared to be the thi semicarbazone of *p*-acetamidobenzaldehyde, or TB1-6 Levaditi,[5] of the Institut Pasteur, Paris, finds that experimental tuberculosis in mice the effect of this d is comparable to that of *p*-aminosalicylic acid, the

Points of View

THE DOCTOR'S PROFESSION*

3asis of a Christian Attitude to Medicine

TORS have to be trained to perform tasks of the oncrete and practical kind. Bullet wounds and ted appendices are not subjects which readily age a taste for abstract speculation. The result most doctors are much more at home in discussing ilar problems than in dealing with general prin- and are suspicious of the facility with which phers and theologians discuss general principles, lly in relation to medicine. Such suspicions may ntly be justified, but they do not do away with cessity for discussing general principles, whether tion to medicine itself or to life as a whole. The t-matter of medicine, the human personality, is a x amalgam of mind and body, and on many s of great medical importance it is impossible to a responsible decision unless the doctor knows his fundamental beliefs about the nature and y of man are.

night, perhaps, be argued[1] that the progress of al study itself has suffered because doctors have nited a conception of what constitutes a practical ach to their subject, so that many aspects of it a neglected and discoveries are not made because lation of the different parts of medicine to one er is not clearly seen. The rudimentary character ch of the study of social medicine may be taken case in point. Whether that is so or not, there e no doubt that too little attention is paid to the n of medical practice to their fundamental beliefs man and his nature, even among those who hold definite views. Christians themselves, as was l in our first essay, are often at fault here. Roman lics have the great advantage of possessing a y-defined position which enables people to know certainty where they stand; but even they com- y state their attitude upon such particular issues as control, abortion, eugenics, and euthanasia with clarity and frequency than they do the fundamental iples upon which those attitudes are based. Most stants have to confess that they have not given ing like enough thought to these subjects. Christ- n medicine today have a duty not merely to make more emphatically clear their position on familiar oversial issues but also why they reach their ion and how their underlying beliefs illumine for their understanding of their work.

rt of the hesitation Christian doctors experience in this is due to the fact that comparatively little nce is available for them. It is true that state- s about the nature of man from a Christian point ew abound, and that many of these are detailed admirable.[2] But such statements are inevitably t man in general, and very little work has been done ie specific question of the Christian doctrine of man affects the work of the doctor.[3] Clearly realising tentative and humble any conclusions reached may be, we shall try to indicate at least how such a task might be approached.

CHRISTIAN DOCTRINE

Christians start from the belief that the universe is not a fortuitous collection of atoms, which possesses no more coherence than that which the unaided rational intelligence is able to impose upon it, but is the sphere of the operation of a God who has made it and who guides and sustains it. This God has made known to mankind His own nature and His purpose for men in a great historical movement of self-revelation which reaches its climax and fulfilment in the person and work of Jesus Christ. All orthodox Christians would be at one in asserting that, in the light of this revelation, man's true nature is seen to be that of a responsible person living in close fellowship with God and striving to bring all his relationships with other people and with the world in which he is set into conformity with God's will as it is made known in Jesus Christ.

There would, however, be divergencies among Christians as to what this conformity involves in some matters. In particular, Catholics would be divided from many Protestants on the question of the status of "the law of nature." This, of course, is something different from what the average student of science understands by a natural law. Catholics would assert that there are certain fundamental truths about man and his relation to the universe in which he is set which can be apprehended by all men, whether they are Christian or not, although the Christian revelation confirms and further illumines them. These truths range from the assertion that there is an objective distinction between right and wrong to quite concrete statements about the nature of the State, or of economic justice, or of the nature of the act of sexual intercourse. Christian obedience involves not merely obedience to the express will of Christ, as declared by Him and as understood by the Church which seeks to live in His Spirit, but also obedience to the natural law. Protestants, however, attach much less importance than do Catholics to this concept of the natural law. Many Protestants would assert that they see no clear evidence for its existence and that the very use of the concept encourages men to claim divine authority for what are in fact highly ambiguous human judgments. They would maintain that in trying to understand man's nature they had to study the content of human experience in precisely the same way as other men did, with no finally determined norms except those which arose out of the revelation given by Christ. This has important practical consequences in regard to the attitude taken up by differing Christian groups on such questions as the rightness or wrongness of the use of contraceptives.

Despite such differences, all orthodox Christians would be entirely united in asserting two things: first, that although all men belong to God the whole race of men have become estranged from Him and in so doing have cut themselves off from the source of life and health, thus becoming corrupted by disease and mortality; secondly, that through Jesus Christ men are reconciled to God, who makes available to them power to overcome the corrupting influence which lies behind disease and mortality. This understanding of human nature in the light of God's dealings with men leads Christians to hold a distinctive attitude to life and death and pain and health which is of great significance for the doctor's understanding of his task.

REVERENCE FOR HUMAN LIFE

First, the Christian doctor has an intense reverence for human life as a precious gift from God. In the beginning "He made all things good" and made man in His own image as the crowning glory of the Creation.

fully treated. Further emboli seemed likely, so after an interval of six weeks the left auricular appendix was excised. During the operation the heart stopped and cardiac massage was required, and a cerebral embolus probably occurred, leaving a left hemiparesis. But there was almost complete recovery, and there have been no further emboli. In the second patient, a man of 52, a successful embolectomy at the bifurcation of the abdominal aorta in December, 1947, was followed by resection of the left auricular appendix in March, 1948. The postoperative course was satisfactory until the ninth day when the patient suddenly died. Pathological study of the resected auricular appendix showed that it was almost certainly the origin of the thrombus.

The clinical diagnosis of an intracardiac thrombus may be very difficult, and no one sign or symptom is pathognomonic. Madden says that the condition may be suspected in cases of (1) coronary thrombosis with peripheral arterial embolism, or (2) chronic valvular heart-disease with auricular fibrillation and either pulmonary or peripheral arterial infarction. In the cases with coronary disease the thrombus is usually ventricular, and it is only in cases of rheumatic heart-disease with mitral stenosis and one or more peripheral arterial occlusions that resection of the left auricular appendix is worth considering.

YOUNG MEMBERS

"ALL education is social education," Mr. George Tomlinson remarks in a foreword to a new Ministry of Education pamphlet,[1] "simply because we are members one of another." The pages which follow are a study of the meaning of citizenship, and its practice in the schools and in after-life. To be a citizen in Athens in the fifth century B.C. was to have clear civic responsibilities. Today we do not live so entirely for and in the State; and this may be a good thing if it leaves us free to grow to be citizens of the world. Nevertheless, the difficult art of living in a community must be acquired in a small way first, even by citizens of a world State.

The child encounters the rule of authority and law first in his own home; he also encounters justice, and perhaps injustice. The kind of injustice—or what seems like injustice—which most children experience at one time or another is the revenge of a parent exasperated by some trivial last straw. Perhaps this in itself is not such bad social training (though the pamphlet does not discuss it), being an epitome of society's response to prolonged irritation; and perhaps the child had better get used to it early, and learn to conduct himself with tact. But such moments of human failure apart, if he is to have a fixed sentiment of respect for justice later, he should be able to count securely on justice as his portion in the home. Even more certainly he should be able to count on affection; and if his home in addition supplies forbearance and understanding he is in a favourable position to build up a stable system of human values.

The pamphlet is remarkable in being the first official document for some time to relate these values directly to religion, and especially to Christianity. Despite the imperfections of Christians and Christian Churches, it suggests, Christianity has been the most enduring civilising force seen in the world. Nevertheless the writer concedes that the love of justice and truth, the appreciation of beauty, with a sense of duty and compassion, can be responsible for achievements "of which all good citizens, without distinction of belief, may be proud."

On the standards formed in the home the child must superimpose the wider and in some ways more exacting standards of the school, since the moral values and ideals he acquires there are generally higher than those of society at large: "the transition from school to is often something of a moral shock." The remedy this, the pamphlet suggests, is not less idealism in and school, but more in daily work and daily pl For hundreds of thousands of young people work dull routine, and leisure means the cinema or the hound track, the palais-de-danse and the par They are bored, listless, emotionally hungry. girls, especially, have no hope of escape from the pattern except through marriage, as Pearl J has pointed out.[2] Better use of leisure time will redress the balance; but the real answer, the pa argues, is better human relations on the spot:

> "To understand other people's point of view; to orders persuasively as between one human being and and to give the reasons that make orders intelligible acceptable; . . . to give a good day's work as a ma ordinary honesty and to . . . reward a good day's work decent working conditions and a fair share of the rewards; to make a bigger sacrifice oneself than those asked of people and to take no credit for it—these are the simple maxims for the lack of which the work of a big org may jolt along with unnecessary friction and waste."

But of course they are not simple at all. To achieve atmosphere in an industry—or for that matter in group of people working together, whether in a h a college, a ship, a theatrical company, or an else—is a complex feat, depending on such things as good will and determination of a small group, a co interest and purpose, and a tradition of service coöperation. It is a weakness of this pamphlet that takes universal good will for granted, and attends the disruptive forces in society only sufficiently imply that we should be better without them.

This one-sided approach is perhaps justified, howe when the practice of citizenship in the schools is disc for teachers need no reminders of the disruptive f in their midst. In our preoccupation with the pro of our day, the pamphlet warns us, we must not ass that they have a like fascination for the young, and carry into the classroom "matters which are beyond understanding and fail to arouse the interest of child They do need, however, to know something of the and national institutions through which we are gov earn our living, and manage our affairs: and an u standing of these things can be gained through studies, in which the children map their own neighhood, examine its industries and agriculture, and study transport system and the goods it exchanges with places. They may visit local institutions and indu and wider horizons still are opened when the "adopts" a farm or a ship, or when—for exam a girls' school council manages a scheme of part-help in hospitals, homes, and small local shops. Ed tion for home life could well extend to household re which interest children of both sexes, and can be used introduce them to facts about items of food, clothi and household equipment—where they come from why some are scarce. Gardening, poultry-keeping, the care of pets, and questions of design and style house equipment, are topics round which teachi explicit or implicit, can range. A science course c teach method, and is often used for that purpose only but it can also be used to teach the scientific background of our civilisation, and the effects of science world food-production, population increase, soil erosi and pest control. Sex education is allowed its pl among other studies; but, as the London County Cou has put it in some recently published notes quoted in pamphlet, "reproduction is an important, but not preponderant feature of the living organism at work it should take its place, but no more than its place, the teaching of biology."

study of medicine is complete without it. But ers in the hands of those who are not influenced Christian understanding of the worth of each al in God's sight are obvious. It can easily men in a contempt for all those elements in life lth which cannot be measured by statistics, and glect for the well-being of those minority groups ust frequently suffer if the standards of the y are raised, while it can often be appallingly to any who do not agree with or stand in the the fulfilment of its programme. The example totalitarian countries can, perhaps, be too easily n the teeth of those in this country who do not Christian profession ; but it is the case that it principles something very much like these that ountries have justified practices like the sterilisa- the "racially impure" and the liquidation of the

third challenge comes from the form of scientific ism which is associated with the names of Bernal ogben and which makes a ready appeal to scientific ians, whether associated with medicine or other s, whose point of view it represents and whose ts it is careful to foster. This attitude has its n the individualism which has been a feature of ean thought since the Renaissance, but it has new force in our own day because of its extension e realm of politics, often under Marxist influence. se man's spiritual nature is not open to investiga- y the only kind of scientific method these writers tand, it is treated by them as of no account in estimation of the worth of men. The individual m is not a person with rights and responsibilities own, who is striving to obey the will of God during ief sojourn here on earth. He is merely one le of the race *Homo sapiens*, striving constantly light of scientific reason to improve its lot, so that rticular generation may justify itself to those yet ne as enlightened and progressive. The life of the dual has no particular value in itself. Its value ds upon its social usefulness as determined by ghtened" and "progressive" opinion. It is to the representatives of this point of view to that they advocate the withdrawal of human from all who do not fall within their definition of usefulness, but it is hard to deny that the logic of position demands this, and the dissemination eir philosophy does much to breed an attitude of mpt for and indifference to the plight of those consider weak, useless, or "reactionary."

SIGNS OF WEAKENING

spect for human life is obviously much more ly threatened by challenges in the political and ary realms today than by anything which is likely ppen in the medical world. Nevertheless, doctors ot afford to be anything but intensely vigilant t this matter. The very basis of their profession is they are the great guardians and preservers of ical life, and they must leave the work of the judges executioners firmly in the hands of others.

n the whole, it is true to assert that the great tradi- s of the profession in this matter are being maintained, there are several ominous signs of weakening against h Christians must uncompromisingly fight. On the side, the vigorous discussion which went on in this try of the propriety of even using the results of riments conducted by Germans in their concentra- camps on patients subjected to barbarous starvation exposure testifies to a healthy ethical sensitivity on subject.[4] On the other side, all doctors are aware of instances in which dying patients have had their end deliberately hastened ; and the attitude of many doctors to the killing of mentally and physically defective infants and to illegal abortion is well known. The prevailing intellectual and spiritual attitude described earlier, which tends to breed in the average student an easy-going cynicism rather than definite convictions of any sort, often inclines to encourage a light-hearted attitude on his part to this solemn trust, an attitude which can easily be encouraged if life and death are treated flippantly by his teachers.

DEATH

The Christian's attitude to death is, of course, closely linked with his attitude towards life. To the Christian death is not the collapse of the physical organism which carries with it the destruction of the personality ; nor is it necessarily, as a surprisingly large number of people believe, the automatic release of the soul, whatever its relation to God on earth, into a condition of eternal bliss. Death for the Christian is the great crisis of human experience. It is the event which makes clear to the strongest and proudest of men that they are frail and mortal creatures who cannot live unto themselves but are always in the hands of the living God. It is the great tragedy of our human existence because in it the deep rift between what we aspire to and what is possible to us stands most vividly revealed. It is also the great trial of the Christian's faith ; for it is only when he stands face to face with the enemy that a man is able to know with assurance whether he believes in the power of the risen Christ and whether that power is able to sustain him through the darkness.

It is fitting, therefore, that the whole demeanour of the doctor in approaching death should be one which recognises the gravity of a great and solemn mystery. This is true of death in general, quite apart from the particular issue of euthanasia, which has already been touched upon. In treating a dying patient the doctor should realise fully that he is being present at an event of great importance, and do the utmost in his power to help the patient to make a good end. It is clearly essential that, provided he shows a proper common sense and sensitivity in doing so, the doctor should inform the patient when his end is near, and strive to make proper provision for the patient to see a priest or minister before it is too late for him to make adequate use of their ministrations. It may not be inappropriate to mention here that the provision made by Catholics for ministering to the spiritual needs of the dying often proves in experience to be much more satisfactory than that made by many Protestants, who sometimes suffer from vagueness and embarrassment. This is a matter which should be looked at very carefully by Protestant ministers. Provided he takes care not to obtrude his own personality unduly, the doctor himself can often be of great help to patients as they face death in these days of spiritual confusion and uncertainty. While the busy doctor who is constantly in attendance upon the dying can hardly be expected to be pondering constantly upon the meaning of death, he would be an insensitive Christian indeed if its challenge and test and promise did not frequently press home upon himself the question of his own relation to his Judge and his Redeemer.

It need hardly be said that Christians should show a proper reverence for the human body in death as in life. The mortal remains of immortal souls are not "stiffs" to be treated like so much horseflesh. The profession has a high tradition in these matters, but it is a tradition which can easily be dissipated by carelessness and thoughtlessness, and it is worth taking trouble to ensure that standards of behaviour in the dissecting-room are always maintained at a high level.

---

[4] See *Lancet*, 1946, ii, 798, 850, 882, 961.

It must be emphasised that it is the desire to cherish and preserve the divine gift of life to man which is the ultimate justification of the profession of medicine from a Christian point of view, and not, as is perhaps more commonly said, the desire to relieve pain and suffering. The parable of the Good Samaritan, which is itself frequently misunderstood, is not the only or the most appropriate text to justify the work of the Christian doctor. The desire to relieve pain and suffering is, of course, included in the other, and is itself part of the Christian's essential work of healing compassion; but to give it the overriding primacy is sometimes to leave open the door to dangerous sentimentality.

Christians believe that each individual human being is infinitely precious in the sight of God, and that, because that is so, the true well-being in God's sight of each individual (which is not the same as his immediate comfort or convenience) cannot be sacrificed to what is conceived by some to be the physical well-being of the race. This conviction of the infinite worth of each particular individual is shared with Christians by many people who do not claim the Christian name but who sometimes put Christians to shame by their ready service of the weakest and most insignificant of their fellows. To the Christian, however, it must always seem that the reasons such people give for holding to their conviction are not very well grounded. He would say that the realisation that each individual soul, however poor or socially ineffective it might be, is infinitely precious is not one which can be rationally deduced from the ordinary experience of those who have humanitarian impulses but one which can only find an adequate justification on the basis of a knowledge of what the divine predestination means.

The word "predestination" has an ominous sound in the layman's ears, but that is largely due to a misunderstanding. Christian predestination does not mean that God has chosen some to be His children and rejected others, according to an unaccountable caprice of His own, so that those who are not chosen do not matter and deserve no consideration. It means that God has a purpose for mankind which He reveals to the individual as a purpose in which he has a specific part. Its nature is such as to emphasise our solidarity with each other in the fulfilment of that purpose, and to remind us that even those who, to our eyes, seem the weakest and most unworthy of creatures, may have a part to play in its fulfilment of which we may at present be unaware. It is because of this that the Christian insists that we have no right to treat lightly the lives of those who perform no useful economic or social function or who are nuisances or menaces to their fellows. He will always remember that the difference between himself, in his personal unity, and the worst and most useless of God's creatures, is at best slight in God's eyes; and he will certainly not presume to try to pass the judgment of God on the worth of the life of a fellow-man while God permits him to live. Thus Christians treat with great reserve all proposals for the sterilisation of the unfit and uncompromisingly resist all proposals for the legalisation of euthanasia, at least as that is commonly interpreted.

It might be argued that this is contradicted by the attitude of at least a large majority of Christians, who would be prepared to justify the wholesale slaughter of large numbers of human beings in war on the ground that it would mean the setting right of intolerable injustice and make life better for future generations, or who would permit the forcible restraint, and if necessary the killing, of a madman running wild through a town and possibly spreading a deadly infectious disease. Without taking sides in the familiar pacifist controversy, it may be claimed that this contradiction is more apparent than real. There is a clear distinction between a situation in which, through the evil actions of men, a

He is merely one le of the race *Homo sapiens*, striving constantly light of scientific reason to improve its lot, so that rticular generation may justify itself to those yet ne as enlightened and progressive. The life of the dual has no particular value in itself. Its value ds upon its social usefulness as determined by ghtened" and "progressive" opinion. It is to the representatives of this point of view to that they advocate the withdrawal of human from all who do not fall within their definition of usefulness, but it is hard to deny that the logic of position demands this, and the dissemination ir philosophy does much to breed an attitude of mpt for and indifference to the plight of those consider weak, useless, or "reactionary."

SIGNS OF WEAKENING

spect for human life is obviously much more ly threatened by challenges in the political and ary realms today than by anything which is likely ppen in the medical world. Nevertheless, doctors ot afford to be anything but intensely vigilant t this matter. The very basis of their profession is they are the great guardians and preservers of ical life, and they must leave the work of the judges executioners firmly in the hands of others.

the whole, it is true to assert that the great tradi- of the profession in this matter are being maintained, there are several ominous signs of weakening against h Christians must uncompromisingly fight. On the side, the vigorous discussion which went on in this itry of the propriety of even using the results of eriments conducted by Germans in their concentra- camps on patients subjected to barbarous starvation exposure testifies to a healthy ethical sensitivity on subject.[4] On the other side, all doctors are aware of instances in which dying patients have had their end deliberately hastened ; and the attitude of many doctors *to the killing of mentally and physically defective infants* and to illegal abortion is well known. The prevailing intellectual and spiritual attitude described earlier, which tends to breed in the average student an easy-going cynicism rather than definite convictions of any sort, often inclines to encourage a light-hearted attitude on his part to this solemn trust, an attitude which can easily be encouraged if life and death are treated flippantly by his teachers.

DEATH

The Christian's attitude to death is, of course, closely linked with his attitude towards life. To the Christian death is not the collapse of the physical organism which carries with it the destruction of the personality ; nor is it necessarily, as a surprisingly large number of people believe, the automatic release of the soul, whatever its relation to God on earth, into a condition of eternal bliss. Death for the Christian is the great crisis of human experience. It is the event which makes clear to the strongest and proudest of men that they are frail and mortal creatures who cannot live unto themselves but are always in the hands of the living God. It is the great tragedy of our human existence because in it the deep rift between what we aspire to and what is possible to us stands most vividly revealed. It is also the great trial of the Christian's faith ; for it is only when he stands face to face with the enemy that a man is able to know with assurance whether he believes in the power of the risen Christ and whether that power is able to sustain him through the darkness.

It is fitting, therefore, that the whole demeanour of the doctor in approaching death should be one which recognises the gravity of a great and solemn mystery. This is true of death in general, quite apart from the particular issue of euthanasia, which has already been touched upon. In treating a dying patient the doctor should realise fully that he is being present at an event of great importance, and do the utmost in his power to help the patient to make a good end. It is clearly essential that, provided he shows a proper common sense and sensitivity in doing so, the doctor should inform the patient when his end is near, and strive to make proper provision for the patient to see a priest or minister before it is too late for him to make adequate use of their ministrations. It may not be inappropriate to mention here that the provision made by Catholics for ministering to the spiritual needs of the dying often proves in experience to be much more satisfactory than that made by many Protestants, who sometimes suffer from vagueness and embarrassment. This is a matter which should be looked at very carefully by Protestant ministers. Provided he takes care not to obtrude his own personality unduly, the doctor himself can often be of great help to patients as they face death in these days of spiritual confusion and uncertainty. While the busy doctor who is constantly in attendance upon the dying can hardly be expected to be pondering constantly upon the meaning of death, he would be an insensitive Christian indeed if its challenge and test and promise did not frequently press home upon himself the question of his own relation to his Judge and his Redeemer.

It need hardly be said that Christians should show a proper reverence for the human body in death as in life. The mortal remains of immortal souls are not "stiffs" to be treated like so much horseflesh. The profession has a high tradition in these matters, but it is a tradition which can easily be dissipated by carelessness and thoughtlessness, and it is worth taking trouble to ensure that standards of behaviour in the dissecting-room are always maintained at a high level.

---

[4] See *Lancet*, 1946, ii, 798, 850, 882, 961.

It must be emphasised that it is the desire to cherish and preserve the divine gift of life to man which is the ultimate justification of the profession of medicine from a Christian point of view, and not, as is perhaps more commonly said, the desire to relieve pain and suffering. The parable of the Good Samaritan, which is itself frequently misunderstood, is not the only or the most appropriate text to justify the work of the Christian doctor. The desire to relieve pain and suffering is, of course, included in the other, and is itself part of the Christian's essential work of healing compassion; but to give it the overriding primacy is sometimes to leave open the door to dangerous sentimentality.

Christians believe that each individual human being is infinitely precious in the sight of God, and that, because that is so, the true well-being in God's sight of each individual (which is not the same as his immediate comfort or convenience) cannot be sacrificed to what is conceived by some to be the physical well-being of the race. This conviction of the infinite worth of each particular individual is shared with Christians by many people who do not claim the Christian name but who sometimes put Christians to shame by their ready service of the weakest and most insignificant of their fellows. To the Christian, however, it must always seem that the reasons such people give for holding to their conviction are not very well grounded. He would say that the realisation that each individual soul, however poor or socially ineffective it might be, is infinitely precious is not one which can be rationally deduced from the ordinary experience of those who have humanitarian impulses but one which can only find an adequate justification on the basis of a knowledge of what the divine predestination means.

The word "predestination" has an ominous sound in the layman's ears, but that is largely due to a misunderstanding. Christian predestination does not mean that God has chosen some to be His children and rejected others, according to an unaccountable caprice of His own, so that those who are not chosen do not matter and deserve no consideration. It means that God has a purpose for mankind which He reveals to the individual as a purpose in which he has a specific part. Its nature is such as to emphasise our solidarity with each other in the fulfilment of that purpose, and to remind us that even those who, to our eyes, seem the weakest and most unworthy of creatures, may have a part to play in its fulfilment of which we may at present be unaware. It is because of this that the Christian insists that we have no right to treat lightly the lives of those who perform no useful economic or social function or who are nuisances or menaces to their fellows. He will always remember that the difference between himself, in his personal unity, and the worst and most useless of God's creatures, is at best slight in God's eyes; and he will certainly not presume to try to pass the judgment of God on the worth of the life of a fellow-man while God permits him to live. Thus Christians treat with great reserve all proposals for the sterilisation of the unfit and uncompromisingly resist all proposals for the legalisation of euthanasia, at least as that is commonly interpreted.

It might be argued that this is contradicted by the attitude of at least a large majority of Christians, who would be prepared to justify the wholesale slaughter of large numbers of human beings in war on the ground that it would mean the setting right of intolerable injustice and make life better for future generations, or who would permit the forcible restraint, and if necessary the killing, of a madman running wild through a town and possibly spreading a deadly infectious disease. Without taking sides in the familiar pacifist controversy, it may be claimed that this contradiction is more apparent than real. There is a clear distinction between a situation in which, through the evil actions of men, a certain number of lives are bound to be lost hard necessity is forced upon us of killing some rest may live, and one where individuals are f sacrifice themselves against their wills or with knowledge either because they serve no clearly social purpose or because they are hindrances some doctors conceive to be the advancement human race.

THREE CHALLENGES

This reverence for each individual human life basic to the whole vocation of the doctor, and is weakened the relationship of confidence be doctor and patient—which is essential if the task is to be adequately performed—is threatened. If a patient has to approach the not with the expectation that the doctor will do thing in his power to save him but with the un that the doctor may condemn him to death, the clearly going to do his utmost to avoid appro doctor. Most doctors recognise this clearly en many slip easily into modes of thinking which, do challenge such a reverence for life. Thr challenges deserve particular mention.

The first challenge is the fruit of an apparently desire on the doctor's part to relieve pain and at almost any cost. When a doctor sees a patie may also be a heavy burden to his relatives, his and the doctor himself, suffering pain from an disease, he may be tempted, sometimes at the s of the patient himself, to use the means which h to hand to shorten the trial. Superficially, attitude may seem to have much with which to co itself. And in some carefully limited circu few Christian doctors would deny the propriety o doses of pain-deadening drugs whose admin might possibly hasten an inevitable end by a few Yet ultimately this attitude is sentimental, and, it is sentimental, dangerous. What was said about the importance of making the Christian's emphasis in medicine reverence for life rather t desire to relieve suffering needs to be borne i here. One of the first results of the decline o Christian faith in any society is the appearance spread humanitarian feeling in reaction agai somewhat over-stern ethical conservatism to whi established Christianity is frequently prone. W seen this in relation to the punishment of crimin to the attitude of public opinion on sexual ma our own day. The reaction is often justified an many great benefits with it; but it has lost defined criteria for distinguishing right from wro its besetting sin is to take the easy way out. In of moral confusion like the present, for the do feel free to hasten the death of his patient shoul disposed to do so is not only to have damaging on the patient's confidence but also to place an int responsibility on the doctor.

The second challenge comes from another which is, up to a point, a healthy and praisewort It is the fruit of a greatly enhanced consciousn men's part of their responsibility for promoti health and material well-being of the race as a and especially of the great unprivileged masses. who are conscious of this responsibility are to b in large numbers among doctors and scientists, a frequently show a sacrificial disregard for the rights as individuals in their anxiety to serv fellows. Such people are always more intere statistics, which throw light on the state of the man, than in the fate of particular indiv From many points of view, this attitude, which i spread and often inspired by genuine idealism, course, realistic and praiseworthy, and no con

Reconstruction

UNITS IN HOSPITAL COSTING*

J. E. STONE
C.B.E., M.C., F.S.A.A.
OR, DIVISION OF HOSPITAL FACILITIES, KING EDWARD'S
HOSPITAL FUND FOR LONDON

ER the accounting regulations of the National 1 Service Act, 1946, the maintenance expenditure ospital is required to be set out under 18 headings, with a few appropriate subheadings. The expen- under each of these headings on outpatients is ted. The resulting balances represent the supposed diture on each item for inpatients. Each of these items is then divided by the average number of ied beds, and the quotient is the "average cost per ied bed." This is the unit of cost to be used to are hospitals one with another. It was the method under the Revised Uniform System of Hospital unts, and it has been the subject of severe criticism any years.

PER OCCUPIED BED

e reasons for this criticism are not theoretical; they ased on the experience of trying, without success, ake comparisons between things which were not arable. And many of the items are not comparable he basis of the occupied bed: for instance the unts deducted for outpatients are approximate, for hospitals maintain separate accounts of expenditure tpatients. Again the different methods of accounting preparation of statistics in use are evident from the nents of witnesses before the Committee on Esti- s. Thus the unit of the cost per occupied bed be, and indeed is, unreliable, and those who rstand the peculiarities of hospital finance do not pt it.

NO COMPARISON

et us take this unit and try to compare two hospitals. Annual Statistical Summaries of King Edward's pital Fund for London (discontinued since the start he National Health Service) show that the lowest per occupied bed in the medical-school hospitals up was £629, and the highest £967, a difference of £338! cannot account for this big difference unless we are ished with much more detail than is contained in general figures in the Summary and the published unts of the hospitals. It may be argued with reason t it is not possible to burden the published accounts h a mass of detail. But the answer is obvious. A hos- l, whether it publishes the details of its accounts not, should always be in a position to furnish m.

t could do so, without any trouble, if it maintained ystem of cost accounts showing the cost of working h ward and department: the unit cost of each: l the constituent elements of this cost. Without s information, it cannot do so, and it is compelled fall back on such replies as: "we have a very large ray department which does a lot of treatment work": ur stores department was reorganised last year": new laboratory was opened which involved a big rease in our staff": "the hospital has been painted"; "a lot more bedding was bought during e year, thus increasing our expenditure unduly for last ar"—as if this kind of item were peculiar to any e hospital. Inquiry might show that the other hospital d done all these things, or some of them, but even en such an inquiry would be inconclusive, for neither spital would be able to produce informative figures.

The wide range of differences in the nature and extent of specialised treatments and services available is another factor which renders this unit of cost practically useless for making comparisons between hospitals. Some hospitals possess elaborate and up-to-date accommodation, and apparatus for radiology and all modern forms of electrical treatment: in others, these facilities may be limited, and the volume of work negligible. On the other hand it might well be that despite limitations the volume of work was even greater. One hospital may have 3 operating-theatres; while another, with the same number of occupied beds, may have 6. Then again, there may be differences in the physical arrangements—area, lay-out, distribution of wards: the number, nature, and proportions of general and special wards; the nature and extent of research work, and of social services. Whether medical records are looked upon as an asset or merely a routine job has a great influence on the cost of that department. The interest, or otherwise, which the authorities take in catering also influences cost. There are differences in the percentage utilisation of available beds, variety and sex of patients, and average length of stay.

AN UNSATISFACTORY UNIT

Where so many different kinds of services are concerned, the average cost per occupied bed calculated on the total expenditure for inpatients is meaningless, and the Voluntary Hospital Commission, in its final report,[1] described it as "at best an unsatisfactory unit." Some hospital activities may, of course, rightly be costed on this basis—e.g., wards; though here again distinction must be made at least between (a) general and special wards, and (b) adult and children's wards. But for most services—operating-theatres, dispensary, X-ray and electrical treatment departments, boiler-house, works department, nurses' home, to mention only a few—it has no statistical value. Ambulance service is the same for a patient brought to the hospital for a four-day stay as for one brought for a month. Twice as many laboratory tests or examinations are not usually carried out for a patient who stays in a hospital for four weeks as for one who stays only a fortnight.

With a uniform system of costing, discussed in our first article,[2] real comparisons would be made possible. With the expenditure on each ward, department, or service available, X-ray department could be compared with X-ray department: kitchen with kitchen: ward with ward; and not only on the total expenditure in each of these units, but also on the unit cost and its constituent elements.

SUGGESTED PLAN

It is not easy to determine exact units of cost; but the following tentative list, which is not exhaustive, may stimulate thought on the subject. The units costs suggested bear no relation to the subject matter of the expenditure—i.e., provisions, surgery, and dispensary—but are determined by the nature of the services covered by the expenditure.

1. Wards	(a) Per occupied bed in respect of all items of expenditure which vary directly with the number of patients under treatment—e.g., provisions, drugs, and dressings.
	(b) Per established bed in respect of all items of expenditure which do not necessarily vary with the number of patients under treatment—e.g., heating, lighting, and cleaning.
2. Operating theatres ..	(a) Per operation performed (weighting may be necessary to allow for adjustment of major and minor operations).
	(b) Per hour operating-theatre in use.
3. Laboratories	Per test or examination.

SUFFERING

Apart from his attitude towards life and death, perhaps the most distinctive of the attitudes of the Christian doctor is that which he holds towards suffering. Why do men suffer? Many answers have been suggested to this perennial question, and we shall hardly be expected to give a comprehensively satisfying answer here.

The Christian knows, however, that suffering is ultimately due to sin. In saying this, it must be emphasised that sin is not primarily the overt acts of wrongdoing committed by particular individuals, for which pain is conceived of as a punishment, but the fundamental estrangement of the whole human race from God the source of its life and health, an estrangement in which we all have part, whether we are called to great suffering or not. But by His suffering and death upon the Cross, Jesus Christ has borne the burden of this sin and opened up the way of reconciliation between God and man. It is the testimony of many who have borne great pain in faith in Him that their suffering has been caught up in His agony, and, through the realisation that they are entering into an understanding of the burden He bore for mankind, has been turned into a privilege and a blessing.[5]

Although suffering can be thus transformed, that does not mean that it is good in itself. However much, as the austere words of the Order for the Visitation of the Sick in the *Book of Common Prayer* remind us, it may be used as an occasion for the Lord's correction and for self-examination and penitence, in itself it is the fruit of our sinful heritage, the sign of the radical disharmony Christ came to set right. Thus, although the conquest of suffering has in itself no redemptive power, the Christian doctor is entitled to regard his work in overcoming it and the disease from which it springs, as part of that reconciling work which Christ initiated and sustains and in which He calls His followers to share. The doctor is, in however humble a way and however unworthy those to whom he ministers may sometimes be, trying to undo the effects of man's estrangement from God, as our Lord Himself did in His works of healing, and in that task he may confidently expect the divine blessing.

> "We have forgotten that Christ took a human body and spent the greater part of His time on earth in healing the sicknesses of it; we have not confessed that the body and the earth are as much redeemed and regenerated by Him as our spirits or intellectual powers; we have not confessed the meaning and power of the Resurrection. A man who fully believes in Christ's Regeneration must regard every physical study as a sacred study—physiology as the most sacred of all."[6]

The beneficent discoveries of modern medicine have a closer relation to the redemptive purpose of Christ than many even among Christian medical men allow. They have come because men have learnt to look upon the human constitution and its environment in a certain way, a way which, as the passage just quoted indicates, is in harmony with the Christian belief in the regeneration of mankind. A firmer grasp of that belief may be the essential precondition of the further development, enrichment, and purification of medical knowledge.

It is in the light of the doctor's reconciling task that the question of the methods which are justifiable for the relieving of pain can best be discussed. It is easy lightly that suffering can be a way to an enric sonality. The doctor knows that that is certain true of many forms of suffering, which are exhausting or enervating or else so intense as to out all thought of everything except themselves. suffering as a privilege is a gift of grace, possible because with God all things are possible. To suffering, or even to take pleasure in suffering, refuse all reasonable means for the alleviation of s is a tempting of God and a deadly form of pride, if not of mental perversion. The habit of intensely religious people of gloating over su fortunately rarely to be met with in the modern cannot be justified on Christian grounds. At the time, the doctor will not go to all lengths to pain. The weapons at his disposal for this pu very powerful, and may be dangerous not only but also, and more insidiously, to human pe itself. The risk, for example, that his patient a victim to drug-addiction as a result of his e "kindness" must be always in his mind. He remember that our primary purpose on earth is make ourselves comfortable with the minimum of and strain but to prepare ourselves for eternity, and this may sometimes, though rarely, lead us to t hard and painful way, in dealing with bodily pain so many other matters, rather than the "sensible the "humanitarian" one.

PURSUIT OF HEALTH

It might appear that the Christian should have thing positive to say about the nature of health. from one point of view, is the doctor's primary Yet, so far, the nature of health remains largely un whether by Christians or anyone else. Most of people who attempt to define it are cranks, who simply by taking one aspect of it and giving it exa importance. A great deal of work clearly needs done on this matter before very much beyond observations about the avoidance of excess and a *mens sana in corpore sano* can be said. We shall ourselves with one remark. The Christian will not the pursuit of bodily health an end in itself nor even take extravagant steps to avoid the risk of ill and injury. He will remember that he lives in a world and that he cannot live fully and satisfact it without accepting the reasonable risks of pain misery which such a life entails. This, in fact, is most doctors do without much thought in regard their own personal habits of life, cheerfully a such hazards as risk of infection when they are u able. There is a healthy strain in Christian which refuses to treat the body and its needs and with excessive seriousness. The Christian doctor w disposed, therefore, to regard a good deal of resp modern medical practice as a form of panderin valetudinarianism, the unhealthy product of an unhea society.

"... in the last resort the reduction of a country's structure *depends upon the willingness of a sufficiently* proportion of its people to discharge what are regar the humbler f . *The citizens* of Britain are all those of other cou —from a sligh . One symptom of for example, is the fact that so great a majority of the in London hospitals are of Irish birth. . . . If the me of a national economy become less willing to serve one a they become collectively *less able* to serve the world be served by it, until their money declines in value and are then all demoted together—i.e., they must all work h and some of them at less genteel occupations, for the return. . . . And after all, it is poetic justice."

—*New English Weekly*, July 28, p

of diphtheria prophylactic as now used, and feeling thing should be done which might conceivably interfere ne success of the present immunisation campaign diphtheria, and not wishing to pre-judge the issue, far not made arrangements for the free supply of lactics against whooping-cough. However, it has no to interfere with the liberty of medical officers of to recommend the use of such prophylactics obtained ommercial sources.

yelitis

unexpected outburst began in the end of May, st six weeks before the usual time, and had the edented incidence of 18 per 100,000, four and times that of the largest epidemic (4 per 100,000 8) previously recorded. The peak occurred in the veek of September when 708 notifications were ed. In the calendar year 7766 notifications (includ- lioencephalitis) were made, and 707 deaths were ed to the disease. The case-fatality was 9·1%, west on record, though probably this figure was ed by the well-recognised tendency to notify mild *on*-paralytic cases when the disease is prevalent. idst all that is unknown or uncertain some facts to have emerged recently. The age-distribution of incidence and fatality is undoubtedly changing, there seems to be a progressive relative reduc- in the susceptibility of children, especially those 5. Only one-third of the cases occurred in children 5; one-third were in children between 5 and 15. ty two-thirds of the deaths were in persons over 15.

FOOD-POISONING

e increase in outbreaks of food-poisoning reported ie Ministry continued, their number reaching 765 pared with 598 in 1946 and 422 in 1945.) Among were 668 known to have been due to salmonellæ. e outbreaks, in which the syndrome was similar to produced by salmonellæ, were due to the Sonne ntery bacillus. Moreover, *S. paratyphi* A, B, and which usually produce illness with the clinical ure of enteric fever, may cause outbreaks of acute to-enteritis. Of the 765 outbreaks 55 were due to hylococci or their toxins. These are usually to be rentiated clinically from the salmonellæ type of -poisoning by the extremely short incubation, of 4 hours, which usually precedes the acute symptoms, rally without pyrexia; the attack ends in rapid very.

y its expert assistance to medical officers and practi- ers, the Public Health Laboratory Service has tly stimulated the reporting to the Ministry of reaks of food-poisoning of all types. So many people adays eat communally in canteens that an infected cle of food is likely to cause illness among a con- rable number of persons in any one outbreak.

o prevent outbreaks the two most important points to t on, besides the elementary one of scrupulous cleanliness, (*a*) that all food-handlers should thoroughly wash their ds and lower arms before touching the food, not only n they begin work but also every time their work is rrupted, and (*b*) that as far as possible the food should eaten as soon as it has been prepared. This latter pre- tion is often difficult to secure in canteens, where meat, es, custard, and puddings, cooked the day before, are n reheated before consumption. Unfortunately the eating does not destroy staphylococcal enterotoxin. If d has to be kept after cooking it should be placed in frigerator as soon as possible to prevent the multiplication ny bacteria it may contain. Several outbreaks have been to defective refrigerators.

VENEREAL DISEASES

A marked fall in new cases suggests that the war-time e of venereal infections may now have turned, and at efficient and rapid treatment, as well as a growing blic awareness of these diseases, will result in a pro- essive decline. The efficacy of modern treatment is well shown by a decrease in infantile congenital syphilis in spite of the record birth-rate in 1947 and the large increase in acquired syphilis during the previous year.

Though the 1947 figures are encouraging, there is no room for complacency. For a fully employed people at peace, the number of new infections is still far too high, and, considering the efficacy of modern treatment, the fall should have been greater than it has been. Penicillin maintains its early promise as a powerful curative agent in both gonorrhœa and syphilis, and there are still no signs that the causative organisms of either disease are becoming resistant to treatment. Nevertheless, the very speed of its action and the ease with which, especially in gonorrhœa, it banishes signs and symptoms, too often breeds a spirit of unhealthy optimism, leading the patient to desert the clinic, sometimes recklessly to expose himself with an unknown consort, before there has been time for adequate tests of cure and the certain exclusion of a double infection. In such circumstances it is often impossible to distinguish between a true relapse and a reinfection.

At one of its earliest meetings the Interim Commission of the World Health Organisation named the venereal diseases, in company with tuberculosis and malaria, as one of the three greatest enemies of the human race, the combating of which deserved the highest priorities.

TUBERCULOSIS

Total deaths from all forms of tuberculosis showed an increase of 3% over 1946, when a new low record was established.

We are reminded that the death-rate from tuberculosis fails to tell the entire story, because tuberculosis, unlike cancer or heart-disease, kills in young adult life or in middle age. In addition, account must be taken of the many years of activity lost by tuberculous patients before death or recovery ensues. The ever-mounting waiting-list for beds could be halved were enough nursing and domestic staff available. The increased number of new cases diagnosed is evidence of activity and awareness on the part of both general practitioners and tuberculosis officers. More than 650,000 civilians were examined by mass radiography during the year, bringing the total so examined since October, 1943, to 2,019,670, of whom more than 94% were found at the time of examination to have no abnormal chest condition. The finding by mass radiography of 257 cases of intrathoracic malignant disease is reported.

A complete review of our general arrangements for the diagnosis, treatment, and aftercare of the tuberculous, and of measures of prevention, is in hand.

NUTRITION

The nation's food-supply, so far as energy-giving foods were concerned, was made worse in 1947 than in earlier years, by the addition, in November, of potatoes to the list of rationed foods. As bread had been rationed late in 1946 this meant that all the main sources of energy were now rationed. The rations, however, of both bread and potatoes were fairly generous, and no evidence came to hand of real privation, though there was doubtless much inconvenience.

Special attention was paid in the clinical surveys to groups of adolescents working in factories. Nothing of a disturbing nature was, however, observed. Indeed the nutritional state of the great majority of the adolescents examined was very satisfactory. In view of this finding it seemed likely that the brunt of any food shortage in families of adolescents and grown-ups was being borne by the housewife. An attempt was accordingly made in London and other cities to assemble for nutritional assessment representative groups of mothers of families of adolescent age and over. It was not found possible to secure representative groups, and while this made any general statement about the nutritional state of this class of mother impossible, the nutrition of those examined was certainly less satisfactory than that of any other group of the population.

The nutritional state of school-children appeared to compare favourably with that of earlier years, but data from 17 areas in different parts of the country showed for the first time since 1941 a slight but definite decline

4. X-ray department	(*a*) Per examination (diagnostic). (*b*) Per treatment.
5. Dispensary	(*a*) Per prescription. (*b*) Per outpatient attendance.
6. Kitchen	(*a*) Per meal. (*b*) Per *basic* meal. (*c*) Per person fed. (Distinction should be made between staff and patients.)
7. Boiler-house	(*a*) Per lb. of steam generated. (*b*) Per lb. of water evaporated.
8. Social service	Per case or per visit.
9. Laundry	(*a*) Per person—(i) staff; (ii) patients. (*b*) Per *basic* article.
10. Ambulance	Per mile run.
11. Nurses' home	Per nurse in residence. (If a training school is included a separate account should be maintained, when the unit cost would be—cost per nurse in training.)
12. Corridors and stairs	Per sq. ft.
13. Gardens and lawns, &c.	Per sq. ft.

The main factors which influence expenditure are: (1) percentage of occupation of available beds; (2) number, and the salaries and wages of staff, which account for 50–60% of the total maintenance cost of the average hospital; (3) engineering and works services 20%); (4) cost of food (excluding cooking and (11%), drugs and dressings (7%). Of these the pe of occupation is affected not only by the inci disease but also by repairs, periodical painting cleaning, during which wards may be closed or closed. It has a particularly important bearing cost per occupied bed. The number of admis the average length of stay are in some measure a tion of the intensity of work at the hospital and demands on the staff, and this in turn tends to the numbers of such staff. The figures of the length of stay in hospital become of paramount tance in ascertaining, not only the cost per bed but also the average cost of treating a patient conclusion. Thus the cost of treating a patient hospital where the average length of stay is consi above the general, though the daily cost is comp low, may be substantially greater than at a h where the average length of stay is low, but the cost is high.

Public Health

STATE OF THE PUBLIC HEALTH

RETROSPECT OF 1947

THE eighth year of austerity, 1947, was a testing year, writes Sir Wilson Jameson, chief medical officer to the Ministry of Health.[1]

Its first three months formed a winter of exceptional severity, which had to be endured by a people who in addition to rationing of food were faced with an unprecedented scarcity of fuel. These three months of snow and bitter cold were followed in April by the heaviest floods for 53 years, which did great damage, killed thousands of sheep and lambs, delayed spring sowing, and threatened the prospect of a good harvest, which was so urgently needed. Immediately after these four months of disastrous weather there followed a period of economic crisis with an ever-increasing dollar deficiency. So acute was the crisis that restrictions more rigorous than any in the war years became necessary. Bread had to be rationed for the first time late in 1946; in September, 1947, the meat ration was reduced; in October the bacon ration was halved; and in November potatoes were rationed. A summer drought accentuated the previous flood damage to the harvest. A steep rise in the prices of foodstuffs and cattle food followed disappointing harvests in many European countries, due to the hard winter and hot dry summer, and in certain crops, notably corn for animal food, in America. Affairs abroad were as depressing as conditions at home.

Nevertheless, the British people made a great recovery in the later months. Production increased, and the year closed more hopefully than might have been expected. Vital statistics and many of the low records of mortality set up in 1946 were again lowered.[2]

THREE INFECTIOUS DISEASES

The three outstanding features of the epidemiology of 1947 are, first, the great reduction in the mortality and incidence of diphtheria; secondly, the threatened invasion by variola major in the first half of the year; and thirdly, the unexpected and distressing epidemic of poliomyelitis.

Smallpox

The numbers of corrected notifications (78) of, and deaths (15) from, smallpox were the highest for many years. These seem to have been due to two importations, one by a soldier direct from India, the other probably seaborne and by a sailor via a French port. Both were of variola major; and the case-mortality was 19%. unsatisfactory feature was that 6 of the cases in persons who, before all others, should have been were not, protected by recent vaccination—a a sanitary inspector, a nurse and a kitchenmaid hospital, a disinfector, and a medical student. departments should review the state of their emp annually as regards immunity. In many cases the features and rash were so much modified by p vaccination as to present great difficulty in di The new laboratory methods proved of great help should be invoked in all cases of doubt. These t outbreaks were successfully limited, without vaccination, by the arduous labours of the various staffs in listing, surveillance, and vaccination of con

Vaccination by the multiple-pressure method was mended by the Ministry as the method of choice late in It is almost completely painless, involves a minimu trauma, and is less likely to be associated with unduly local reactions or septic complications. It is hoped the use of this method will increase the percentage of vaccinated during their first year, for the importan primary vaccination in infancy to the child and to the munity is well established. Postponement of primary tion to a later age; or until it becomes necessary for f travel or military service or from contact with probably entails far more inconvenience and leave community quite unnecessarily vulnerable to smallpox

Diphtheria

For the sixth successive year the number of d was the lowest yet recorded. Moreover, the 244 d at all ages numbered but a little more than half (472) in 1946, and less than one-tenth of the a in the ten years 1931–40. The number of cases in 1947 is also the lowest ever recorded, less than the number in 1946. For the ten years 1931–4 average annual number of *original* notifications about 55,300. The total of original notifications (1 for 1947 therefore is nearly 45,000 below that av This meant a great saving of hospital beds and It released some 2500 nurses for other work, and financial saving was considerable. Such are the already reaped of the intensive immunisation camp

Dr. Percy Stocks shows that the protection aff by immunisation against dying from diphtheria considerably greater than the protection against tracting the disease. The practice of administ "boosting" doses, particularly at entry to school, w markedly increase the protection against attack.

The use of combined diphtheria and whooping- immunisation has many advocates; but the Ministr view of the excellent results given by the distribution

rvice mess made it natural to try alcohol as a but I am not a drinking man and the return to y was always so shattering that I gave it up, ough mild intoxication blended with the anxiety a way as to make one feel more normal.

e visual obsessions were terrifying, both because apparent meaninglessness, and because of their dent existence. I often had the most acute for instance, of a hammer and screwdriver g away at my skull, or of my skull being forced and spat into, perhaps at a moment when an r would only have noted [illegible] ng peration or talking to my [illegible] I be opening an abdomen, for instance, and would e most vivid hallucinosis of eyes looking at me from the cavity. At night I was driven to distraction ughts of self-destruction—not by the wish to do by an accurate representation of suicide in various sant ways—and I took elaborate precautions to against this. Silly jingles and rhyming phrases emselves over and over again in my head. Every d again, of course, all this boiled up to an unbear- tensity. Then I rang up the regional Service atrist and got it off my chest with a good deal ng and abreaction generally. This was a relief, ly for the time. He himself was an understanding but it was his duty to keep in the Service an who was still capable of performing his duties, at was all the treatment I got. Perhaps he was At any rate I knew nothing of psychiatry then, thing about treatment, which I assumed did not or my sort of trouble. Oddly enough, my surgical lid not suffer. If anything, I operated during this better than ever before or since, for it was the best f occupational therapy. Only at the very end of ar did I begin to feel unable to carry on, for once ce I had to get my anæsthetist to sew up for me; hough I am an atheist I several times prayed. an operation, for help in dealing with the life that my hands. Lack of occupation was the worst , and since periods of complete inaction always p in the Services they formed a recurrent terror. ng motor journeys from hospital and clinics over area were almost unendurable, as it was impossible anything but "sweat it out." Even reading, a standby, had become impossible. At any time ight be seized by the panic fear that, quite suddenly, hing in the outside world would go wrong, that ould begin to hear or see quite abnormal and ounds and sights; and sometimes these panic would become so acute that it was almost impos- to stop oneself running out into the road in flight this formless terror.

en I had been ill in this way for many months ature of the illness began to change. One can't being frightened for ever, and depersonalisation This, again, is difficult to describe to others. night best illustrate it, perhaps, by saying that it feeling of anonymity. I remember that I felt the time, and very acutely at some times. It ll so odd. I might be having a conversation with a or eating a meal, yet without any sense of my dentity or indeed of any identity. At such moments ht other human company desperately, for if others nised me and knew my name and treated me as son, then I must exist. Loneliness was unbearable, ortunately the unit had attached to it a Catholic who knew something of my sufferings and tried are my burdens. My heart goes out to him now ever I recall this period. But the depersonalisation ne worse and worse, and there was an acute stage , after three nights without sleep, a fundamental ation seemed to have taken place from the world other people inhabited. After that I lived, talked, acted, but I felt like a walking ghost. I *was* in limbo. Everything seemed to happen at one remove. Listening to the wireless, I first registered the sounds and then had to translate them. In London once, on leave, and looking into Lewis's window, I noticed a book entitled *Vertebrate Photoreceptors* and thought miserably what an accurate description of my own eyes this was, so little was I moved or interested by what my retinæ recorded.

And yet, all through this dreadful time, there was one in my mind who observed my derangement with detachment and with sanity, and I think this is what sustained me. Many times I thought of suicide, or longed for the help of religion. But I had no courage for the first or belief for the second. Though in the end I came to believe in my actual madness, the fact that part of my mind still seemed capable of critical comment saved me. Eventually I made a special journey to consult a psychiatrist who was an old friend, and was referred to a leading psycho-analyst, who made it clear quite casually that my illness was nothing exceptional, that I was far from mad, and that I could be cured by treatment as an outpatient. This was the first time I had ever even entertained the possibility of cure, and the effect was overwhelming. First I had to be invalided from the Service and then to find a suitably placed analyst, but after a couple of months these objects were secured and I began the strange, disturbing, but so rewarding process which lasted, with interruptions, for the next four years.

My analysis was conducted by a woman, and I was able to go on with a minor surgical job in the country; but it meant travelling 25 miles each way every weekday evening for the first few months. The financial burden was severe, though not, I imagine, as much as it would be today. This is no place to describe the process of analysis. It has its ups and downs, its periods of violent hatred or affection for the analyst—the negative and positive transferences, as they are called—and the times when we had to abandon it altogether for a time for lack of progress. But infinitely satisfying were the moments when intellectual understanding of the origin of a symptom fused with emotional acceptance to mark a step back to the real world, a step accompanied by a return of reality to the impressions my sense organs brought me. Now that I was in analysis and could talk it out, the fear of madness gradually receded, though it was another year before it became inconspicuous. At the same time my social behaviour became more unstable, freed from its previous rigid restraint. At no time did I stop working, and I accomplished with success many activities outside the purely surgical field.

Family life was difficult, of course, and my wife and children must have found it very trying at times. Looking back, I feel I owe my salvation first to a devoted wife and second to my analyst. What would have happened without these two I prefer not to think about. Now, cured and nearly a decade after falling ill, I occupy a busy, eminent, and satisfying position in my own field. I have moments when the shadow of a symptom returns, but now I can always detect for myself the immediate cause in some recent happening or incident. Above all, I would like to say here, analysis does not merely restore one to normal. It makes one normal for the first time. I feel now that I really understand life and living and that I have a real philosophy of life, and I wonder at the immature individual I used to be. I realise that neurosis is an untutored essay in self-analysis, and I have a profound contempt for the physical treatment, and particularly for the surgical treatment, of mental disorder. Above all, I have retained enough of my experiences to be able to remind my students and nurses that a neurotic's sufferings are real sufferings and his complaints genuine.

in weight. The rations and allowances for the schoolchild, including school meals, had not changed materially since 1945, and the proportion of children taking school meals had increased from 36·3 to 50·4% and that of those taking school milk from 73 to 87·5%. Hence the cause of the decline in weight is not clear.

In introducing this 24th annual report of a chief medical officer to the Ministry, Sir Wilson Jameson says that, as before, it is the work of many writers, named and unnamed. Dr. J. Alison Glover has again been editor.

Poliomyelitis

The number of notifications in England and Wales for the week ended July 30 was poliomyelitis 147 (96), polioencephalitis 22 (3). Figures for the previous week are shown in parentheses. Counties reporting more than one case (poliomyelitis and polioencephalitis together) were: London 20 (7), Bedford 2 (0), Berkshire 2 (3), Cambridge 2 (1), Cheshire 6 (0), Cornwall 8 (1), Dorset 2 (0), Durham 2 (1), Essex 8 (4), Gloucester 3 (2), Hertford 3 (1), Kent 3 (0), Lancashire 12 (8), Leicestershire 5 (6), Lincolnshire, Lindsey 4 (1), Middlesex 13 (11), Nottinghamshire 3 (1), Oxfordshire 2 (0), Southampton 7 (8), Suffolk West 4 (3), Sussex West 4 (1), Warwick 6 (1), Westmorland 2 (0), Yorkshire, East Riding 2 (1), Yorkshire, West Riding 21 (17), Denbigh 2 (0), Glamorgan 3 (0), Monmouthshire 2 (0).

The rise in notifications was considerable, and it is unlikely that a consistent fall can be expected yet. But it must be remembered that, in comparison with 1947, the rise this year has been irregular, and that in the corresponding week of 1947 there were 302 notifications of poliomyelitis and 34 of polioencephalitis. In 1947 the peak was reached in the week ended Sept. 6 (36th week): but notifications in the week ended Aug. 16 (33rd week) were almost as high, and there was a small recession in the two intervening weeks.

March Quarter

With its issue for the first quarter of 1949 the Registrar-General's Quarterly Return for England and Wales inaugurates a second century of publication. A note at the beginning mentions "an interesting social change" since 1849—namely, that "whereas in those days most marriages took place in the fourth quarter 'which follows harvest, includes Christmas, and is the marrying season in England,' and most births were in the first quarter, nowadays most marriages are in the third quarter and most births in the second."

Provisional vital statistics for the March quarter, 1949, show that the infant-mortality and stillbirth rates were again the lowest for any March quarter. The infant-mortality rate was 40 per thousand related live births, compared with 41 in the corresponding period of 1948 and an average of 64 for the first quarters of the ten years 1938–47. At 23·1 per thousand total live and still births the stillbirth rate was 1·3 lower than a year before. The live-birth-rate was 17·4 per thousand total population, compared with 18·7 in the March quarter, 1948. The death-rate of 15·0 per thousand represented an increase of 2·7 over the record low rate for the same period last year and was 0·2 above the average for the March quarters of 1943–47.

Population.—In the age-group 20–40 in the total population (including the Armed Forces) there is very little difference between the numbers of the two sexes (men 6,564,000; women, 6,541,000). From age 60 onwards the women outnumber the men by a million (women, 3,906,000; 2,910,000), and from age 80 onwards women are nearly twice as numerous as men (women, 412,000; men, 228,000). Persons under 20 years of age total 12,368,000; those aged 20 years and under 60 number 24,592,000; and there are 6,816,000 people 60 years of age and over.

Deaths in 1944

The last of the war-time arrears of the Medical Tables volumes of the Registrar-General's Statistical Review, that for 1944, has now appeared.[1] Those for 1945, 1946, and 1947 have already been published.

Disabilities

36. ANXIETY NEUROSIS—I

DURING the middle years of the second w I felt myself becoming increasingly uneasy sheltered occupation of a civilian surgeon, wa procession of house-surgeons and registrars c into the Forces. Eventually I volunteered, an a surprising amount of difficulty with my e and the authorities generally, managed to get of the Services in my own specialty. Looki now, I suppose this guilty urge to get into was the first symptom; at the time it seemed t thing to do, though I am a very domestic and always unhappy away from my wife and The first month or two of training and postin novel and exciting, like going to school for t time; and though, like everyone else, I had of being sent overseas and the risks this implie were not unduly magnified. Then I settled do a long and very comfortable posting at a Service h and without warning the thing struck me.

It is as difficult to describe to others what a anxiety state feels like as to convey to the inexp the feeling of falling in love. Perhaps the most teristic impression is the constant state of cause apparently meaningless alarm. You feel as if y on the battlefield or had stumbled against a wild in the dark, and all the time you are conversi your fellows in normal peaceful surroundings a forming duties you have done for years. W your head feels vague and immense and stuffe cotton-wool; it is difficult, and trying, to conce and, most frightening of all, the quality of your appreciation of the universe undergoes an change.

I found the visual disturbances most un Everything looked flat, two-dimensional, and I often used to stare at clouds and fields and w to come real again; and even now, cured an afterwards, these feelings of visual unreality lin I *recall that one of your peripatetic corresp* once wrote about the bitter complaints of his n that everything looked like a theatrical backdr is an accurate description. After vainly trying back to normal seeing, and getting refracted improvement, I noted similar changes in the senses. As the long humid summer days drag with their loads of terror and obsession, hear became dulled, and I wondered if I was drifti some limbo a stage removed from the outside Always, at every waking moment which was not o with some urgent and difficult task, my mi haunted by the thought, first that I might be mad, later that madness was only a matter o In the end, after a year of this, with mental distu of an unpleasant nature which will be mentione moment, I firmly believed that I was in fact ma longed only to get home for a few last weeks w family before the end. Another disconcerting times terrifying symptom was a loss of control o thinking processes, and the intrusion of though images of apparently spontaneous origin. T itself became verbalised, which it had never been l and grotesque and frightening images, often of hallucinatory intensity, appeared. These were acute in the drowsy pre-sleep period; but for m I was able to sleep soundly without dreaming through the miserable days I longed for the nig release. I managed to do without any drugs for the whole of the year, and then, when sleep too to fail, I had recourse to 'Medinal.' The atmo

Letters to the Editor

THE R.M.B.F.

-For the first time in the history of the Royal Benevolent Fund, the chairman's report is nt to every member of the profession in England, d, and Wales. The committee has felt justified g this step as the fund is essentially the profes- wn Benevolent Fund and all members of the on should be informed of the useful and valuable hich is being done to alleviate the distress which ithin our own ranks.

all your readers to consider the report as one of l importance and to help the work to be continued true spirit of brotherhood by giving generously e who are in adversity.

Fund receives much help from many, but to who are not subscribers I make this appeal: e support your own Benevolent Fund by a sub- n, large or small. Help to make the Fund of our great and noble profession by having sonal support of every medical practitioner."

Medical Benevolent Fund,
lliol House, Manor Field's,
London, S.W.5.

WEBB-JOHNSON
President.

OSTRACISM OF THE TUBERCULOUS

—Recent correspondence shows the need for a true iation of the part played by the tubercle bacillus community.

are desperately short of industrial man-power, and the important age-groups 15–50, tuberculosis is ly responsible for a mortality far greater than that any other disease. This severe, and recurrent, nic loss, according to a prediction of the Royal ission on Population, may become even greater. umber of young adults, aged 15–40, is likely to e by 1,400,000 over the next fifteen years!

majority of new cases of phthisis are being diag- in a stage too late for effective treatment; and of all deaths from pulmonary tuberculosis through- ne country, half are still occurring within a year of ation. Delay in diagnosis leads to: (i) death of atient; (ii) spread of infection, and further cases erculosis: and (iii) blocking of scarce beds with iced cases. The refusal of general hospitals to t cases of phthisis is largely responsible for the it unsatisfactory position. Success in our fight st this disease will only be won by the combined s of a team. The general practitioner, as the ator of diagnosis, is the most important member is team. Thousands of young postgraduates, how- are entering practice with little experience of culosis and no appreciation of the clinical features ly disease. As Dr. Foster-Carter says, "the teaching tals, in particular, should set an example to others." mportance of the disease to the community warrants llocation of a proportion of available beds in every eneral hospital.

der the direction of Dr. H. Joules, the experience he Central Middlesex Hospital has shown con- vely that, with adequate precautions, as stressed by nell, it is quite safe to nurse patients in tuberculosis s in a general hospital. Patients suffering from active onary tuberculosis are admitted to the tuberculosis is from the Willesden Chest Clinic. Emergency are kept free in the male and female wards, and these are transferred immediately any *open* cases of rculosis from the general medical or surgical wards. h cases are consistently found in every general ital and are largely responsible for the infection usceptible nursing staff.) Mantoux-negative nurses not allowed to work in the tuberculosis wards. The beds are adequately spaced, with free ventilation; floors are oiled; and nursing staff must wear masks and gowns while making beds and attending to patients. Sputum pots are handled by porters and cleansed in steam sterilisers on the block. Both the Mantoux conversion-rate, and the incidence of tuberculosis, amongst nurses at the Central Middlesex Hospital are thus kept well below the average for a hospital of this size. Lastly, there is no feeling of ostracism in the patients, who, together with the medical and the nursing staff, gain substantially from coöperation with other departments of the hospital; and practitioners of the area are encouraged to feel that early diagnosis will be followed by prompt treatment.

The advent of B.C.G. will not obviate the constant need for such precepts in the future!

Willesden Chest Clinic,
London, N.W.10.

C. H. C. TOUSSAINT.

SPLENECTOMY AND THE HÆMATOLOGIST

SIR,—Disputation concerning terms is seldom fruitful; but words have their uses, which I feel are abused in your leading article of Aug. 6, when you first categorically state that "the hæmatologist, on whom these surgeons rely, is not a clinical pathologist" and then proceed to define the said hæmatologist as a "clinician who is capable of making his own assessment and if necessary a personal interpretation of the hæmatological data and material." This I submit, Sir, is a very perfect definition of the clinical pathologist: it is the end to which all present training in clinical pathology in this country is directed and the aim of all those making through it their approach to medicine. The terms "hæmatologist" and "clinical pathologist" are not, as you appear to imply, incompatible.

The Royal Hospital, Wolverhampton.

S. C. DYKE.

HEARING-AIDS

SIR,—On the face of it, and to those without serious knowledge of the subject, your article last week on hearing-aids would appear to be a reasoned essay, and presumably an attempt to answer the leaflet published by the hearing-aid advisory committee of the British Association of the Hard of Hearing, of which I was the author.

You say that steps have already been taken to meet some of the complaints about the 'Medresco,' but the point at issue is that with all the modern knowledge of hearing-aids there should never have arisen any cause for such complaints. To produce, for instance, such an ugly ridiculous thing as the "plug-in" type of attachment for the earpiece, with its rubber nipple, when a standard moulded insert, made in many sizes, was available at the low figure of 1s. 9d. each, was surely the height of folly. These plug-in types are still being issued with the promise of a moulded earpiece at some distant date. Many people issued with the plug-in type are buying the standard moulded type as a temporary measure against the time when they are properly fitted.

Then, surely, a test by an experienced user of hearing-aids as they came off the production lines would have prevented many thousands of faulty aids reaching the hospitals to waste the time of exasperated hospital technicians.

Before the introduction of the medresco, clinics were careful about issuing an electrical aid to cases of nerve-deafness: now these appear to be issued indiscriminately. Fortunately I do not suffer from nerve-deafness, but, since I mix with the hard-of-hearing, I am able to study the reactions of a people suffering from severe nerve-deafness. In most cases, all they get is a tremendous increase of general sound, and, although they are able to hear someone speaking, are unable to pick out the words. The general increase in noise cannot be helpful to them,

In England Now

A Running Commentary by Peripatetic Correspondents

It was intolerably hot and the carriage was full. The train dragged slowly along, stopping at short intervals as if to mop its brow. Conversation turned on the advantages of possessing a pair of seven-league boots. In the circumstances unanimity might have been anticipated, but a beady-eyed little man in one corner—I noticed that he had pointed ears—came down sharply on the other side. "With all respect, gentlemen," he said, "have you seriously considered the arguments against?" Some of the more somnolent woke up and stared at him glassily but with faint interest. "You see," the little man went on, "the trouble with these boots is that you have to go seven leagues at every stride and that may be inconvenient. If your destination is twenty-one miles away, or any multiple of twenty-one, you are, I agree, on velvet. But suppose you want to go to a place *less* than twenty-one miles away, or somewhere more distant which is not a multiple of twenty-one miles away. You have to make a complicated zig-zag cross-country journey. What is more, you must work out your mileage accurately before you start. And there are worse dangers. I once had a friend who owned a pair of these boots. It is a sad story. He wanted to walk from Land's End to John o' Groats but he miscalculated the mileage. The unhappy result was that his last stride took him a mile out to sea and he was drowned."

The train creaked into a station and jolted to a stop. "Poughill!" shouted the guard. The little man jumped to his feet. "I get out here, gentlemen," he said. "Good-bye." He nodded pleasantly, waved, and disappeared through the closed door.

"Poughill," said somebody. "What a curious name."

"Yes," said a bearded scholarly-looking man in the far corner. "It's a corruption of Puck's Hill," you know.

* * *

The B.M.A. holds a nice little party every year, but it is chicken-feed compared to the annual congress of the A.M.A. in Atlantic City. The city itself must be unique. Along its beautiful sands stretches the famous wooden "boardwalk"—for 8 miles. It is hot walking, so you can be pushed gently along this in a little wicker chair by *a perspiring darkie, if you've enough dollars.* Alternative methods of transport were suggested by a hire advertisement for "bicycles, tricycles, and bi-sexuals." Inquiry proved the last to be a local colloquialism for the tandem. The rest of the city consists of the booths and shops which line this celebrated thoroughfare; the many piers (Steel pier, Million-dollar pier, &c.); some hundred of hotels, ranging from the super to the squalid; and the largest convention hall in the world, into which 20,000 people can on occasion be packed. There are of course some other buildings, which include the continent's largest sea-food restaurant (3200, excluding our party, were dining we heard!), and perhaps a dozen score of churches and chapels, lying in wait presumably for repentant visiting sinners. An alternative measure of dealing with this problem appears, however, to be provided by the unusually heavy armament carried by the local police. The economic life of the city seems to be cleverly balanced between the "Blackpool" component, which carries it through the summer, and the *conventions and* congresses, dear to the male American heart, which keep it populated throughout the rest of the year.

On our way to the hall to register—it was Sunday morning—we were edified to observe an aeroplane flying low along the shore, trailing a banner with what seemed at first the strange device "K.O.V.D." (Knock Out V.D.!). This was followed by another which more [illegible] ommended us to buy and use —'s [illegible] Later in the day they wrote "happy [illegible] ke.

We attended, together with 15,000 other doctors and wives, the new president's speech of welcome. The dais was backed with an enormous reproduction of Sir Luke Fildes's picture "The Doctor," with a caption advising us [illegible]fos part of the no-socialised-medicine campaign—to "take politics out of this picture." We sat up as the president led off by informing us in stentorian tones that his young and virile nation is in need of no outworn relics of the effete social system favoured by decadent so-called democracies. This seemed good so we stayed; but the rest was just ordinary p stuff. The madrigal singers, who had been much and who were to have followed him, did not ap there were some more speeches.

The exhibition itself was like our own Medical tion but on a colossal scale. There were also differences—for instance, the glamorous coll live semi-nudes who reclined on a beach fl U.V.L.; I think they were advertising a Miami or something. Then there was the large car which a drug-house will present to the who writes the prescription with the lucky num the ensuing year. The alcohol-ometer (for home use). The naval captain and army colonel who over a joint Service exhibit, each with a 'C bottle and straw in hand. The queues of thirsty waiting for a "handout" of babies' orange- next door of 'Camel' cigarettes. Upstairs one clinical demonstrations from a Philadelphia h the colour television screens, or hear high- lectures on diabetes, arthritis (including Com and cardiac failure. Out of hours hospitality was and we were made extremely welcome. To coin a a good time was had by all.

* * *

"And what do you think of the Health doctor?" is still, apart from the "What is really with me?" type, the commonest question we get nowadays. The possible answers are many, but saves sending in bills" seems as good as any. It a joy not to have to settle down the last week of quarter to send out a few hundred accounts. methodically minded it may be simple enough, people like me who are invariably about 12 weeks in their entries it isn't much fun. What n Victoria Road is Mrs. Jones? I suppose I t would never forget her address, but it's gone and I go inquiring at all the front doors in the street for a wearing a glass eye who hasn't paid her bill. Wh, I charge Mrs. Smith 7*s.* 0*d.* for one visit and 10*s.* the next? Perhaps the latter was a night call or it was really my own exasperation. Anyhow it's ago and I've forgotten. Yes I'm glad bill-sen over. Come to think of it, the actual *mention* of cash seems taboo now we are Bevan Boys. We innumerable forms. We may even write " service" on our maternity accounts, but figures discreetly left out. Perhaps that is why our q cheques with the higher mathematical sum accompanies them are still a bit incomprehensible average G.P.

* * *

I shall be a lot more sympathetic with my de patients in future. I have just undergone an ex traumatic experience and show all the cha symptoms of reactive depression. I have a de expression and appearance, complain of a lowe spirits, cannot concentrate on my work, and difficult to respond quickly to a stimulus—a sy known as psychomotor retardation. All these sym are subjectively appreciated as a continuous preoc tion with painful thoughts. Though I do not feel su life appears stale and profitless; so I can really stand why people can be tempted to end it. The c fulness and silly laughter of others seems unreal, their sympathy is a mockery and brings no comfor may ask a colleague to give me an ether abreaction this treatment, the people who are the cause of misfortunes would be presented to my mind in s manner that I could express fully my feelings of sion towards them. If all went well, this would my symptoms. But on second thoughts I might as wait until the results are out, and anyway I can another shot in six months' time.

* * *

The anxiety of some of us about grading, awards, and so on recalls to my mind that in 158 pay of a surgeon in the Royal Navy was 15*s.* a m raised in 1602 to 20*s.*; that the trumpeter drew the pay as the surgeon; and that the smaller ships given the choice whether they would carry a surgeo a trumpeter—they could not have both.

s, senior medical officers, and junior medical ; to the plain man it would seem possible to hese factors into a simple system of three groups, th its own salary scale, thus—

nsultants and medical superintendents ;
ecialists and senior medical officers ;
gistrars and junior medical officers ;

se are the analogous grades in the two original s.

, then, was this not done? The answer is an ; but a dismal one: because it would not have n accordance with the professional values of At the moment the voluntary-hospital system e ascendant, and voluntary-hospital ideals prevail current assessments and gradings, in the vaunted ance of medical counsel and the denunciation of l control, and in the endeavour to degrade the l superintendent. Nevertheless, eventually, the uthority system will succeed: because it has been ed in the vice of official demands, tested and proved furnace of official needs and requirements; because tional Health Service, when all is said and done, fficial, and not a voluntary hospital, service—and s its destiny. Wise, therefore, should we be to n the medical superintendent and the consultant qual and co-extensive, similar though not identical. would we? I wonder.

A Local Authority Officer.

LACRIMATION AND MICTURITION

—Dr. Vernon R. Pickles's communication (July 9) the association of lacrimation and micturition, niniscent of the euphemistic "shedding a tear," ts me to say that for years it has been my practice k all patients suffering from epiphora, not if rition had been disturbed, but—so fruitful has he inquiry—what particular form it took. Polyuria ncreased frequency, of course, are the usual com- s, but idiosyncrasies vary; the symptoms may be , and questioning demands insight and sympathy. n intuitive methods, though based upon long years servation, cannot be commended scientifically, and not prepared to formulate rules.

er all, the association should not be surprising. ickles does not give the sex of his case, and tells othing of his subject's personality—an important ion where these functions are being discussed, the commonest cause of lacrimation is emotion. may or may not be conscious and produces variable ts according to age; years bring a taboo. Hence, ips, the apparent rarity of the phenomenon recorded r. Pickles. The effect of emotion upon the secretion ine is also well known. In some mysterious way may account for the modern avoidance of the ed onomatopœic word "piss," which nevertheless ound biblical sanction. Present-day children wee- it needs only the addition of a "p" and they d a tear." May I go further and urge the desirability nsidering to what extent lacrimal obstruction may psychogenetic origin? But that is a far "cry."

Greece curative weeping is practised for con- tivitis, and according to Dr. T. Stephanides,[1] n tears fail to deal adequately with this and other itions the eye is bathed with fresh urine from a cow. universal foster-mother becomes a pharmacy. I am not quite sure that the alternative "fresh leaves pounded into a mortar and placed as a press on the eye" is not bringing the same ideas into ionship; the product, often suggestively pale w, of the vine is notoriously provocative of tears urine.

rtsmouth. W. S. Inman.

LIVER EXTRACTS IN PERNICIOUS ANÆMIA

Sir,—I do not propose to reply to all the points raised by Dr. Ewing in his letter of July 23, but I would like to call attention to one or two.

In the first place, there seems no doubt that liver extract resembles insulin and many other biological products in that certain patients respond better to (or are less worried by side-effects of) the products of certain manufacturers, apart altogether from the measurable therapeutic potency of the extract in question.

Dr. Ewing seems to imply that American liver extracts are, in general, more effective than those manufactured in this country, and that this is due to their being prepared from "fresh and healthy liver." Perhaps, however, his attention has not been drawn to an article by Rickes et al.[1] in which they report the results of their estimations of vitamin B_{12} in six American commercial liver extracts for parenteral use made by four different manufacturers. These extracts show a variation in B_{12} content, between 1·2 and 14·0 microgrammes per millilitre, although all were claimed to contain 15 *U.S.P.* units per millilitre. In another paper, by Haden and Bortz,[2] the clinical potencies of 15 *U.S.P.* unit liver preparations made by different American manufacturers are said to show wide differences. I understand that a paper will be published in the near future in which similar results of the assay of vitamin B_{12} in British and American commercial extracts will be compared and similar differences shown.

Dr. Ewing's suggestion that the opinions of representatives of commercial houses manufacturing liver extract in this country on the satisfactory nature of the livers from which their extracts are made would be neither competent nor disinterested, strikes me as curious. Surely the commercial firms would do everything in their power to obtain a raw material satisfactory for their purposes!

Weldon Dalrymple-Champneys.

Ministry of Health, London, S.W.1.

PREGNANEDIOL IN URINE

Sir,—The observations made by Dr. David Stern at the Congress of Obstetrics and Gynæcology, and restated by him in your issue of July 30, were, I thought, of considerable interest. But for the lengthiness of the congress discussion, no doubt the introducers would have been afforded an opportunity for response, in which case I would have said then, inter alia, what I propose to suggest now.

If the constancy of pregnanediol output per hour (over short periods) as found by Dr. Stern, and its close correlation with the 24-hour output, can be confirmed, then clearly an important point will have been established. For such confirmation both his own further investigations (for he admits that his series is as yet too small to justify publishing figures) and those of others will be necessary. I am doubtful, however, as to whether the value of this demonstration will be as great from the practical as from the theoretical aspect, since utilisation of the principle would involve the accurate noting by the patient (in the case of an outpatient) of the time when the bladder was last emptied before the specimen was collected, as well as the time the actual collection was made; and in addition the collection would have to be the entire bladder contents. Neither of these requirements would seem to be prohibitive, but my own experience of the results of requests to patients to follow even simpler instructions leads me to conclude that imperfect collection, or inaccurate recording of times (or its omission altogether), are not unlikely; and this would and this can be observed by their movements in continually raising or lowering the volume of their aid, or, in fact, eventually switching off and resorting to lip-reading and immediately being able to understand what is said.

[1] *Lancet*, 1949, i, p. 115.

[1] Rickes, E. L., Brink, N. G., Koniuszi, F. R., Wood, T. R., Folkers, K. *Science*, 1948, 107, 396.
[2] Haden, R. L., Bortz, D. W. *J. Amer. med. Ass.*, 1948, 138, 870.

Your article states that the B.A.H.O.H. estimate the need at 150,000; this is not the case, the estimate was given by the Ministry of Health, and indeed it is a mystery how they arrived at this figure. It will be surprising if the eventual figure is not nearer the 500,000 mark.

We are asked to view the situation in perspective, although what is meant by this is not quite clear, and the statement is made that "it is a waste of time and money to give people aids without at the same time giving them proper training in their use." With this we heartily agree, but *unfortunately that is exactly what has been done from the very commencement of the issue of medresco:* no training whatever in the use of aids has been given, and therefore this cannot be used as an excuse for delay. You admit that there is a crisis, and state that one clinic has had to close the waiting-list with little prospect of opening again for nine months. It can be added here that the waiting-lists for repairs are beginning to reach the lengths of those for new aids. One year, or two, or even more is a long time to wait for an aid when you are old, for you may be dead before you get it, or thrown, unknowledgeable and unprotected, on to a seller's market to become the victim of unscrupulous advertising. Instead of protecting the hard-of-hearing against exploitation, the present chaotic position is doing exactly the opposite.

What has transpired since July 5, 1948? The annual budget for the hearing-aid side of the health service is £5,000,000. In the first year some 27,000 hearing-aids were issued, and according to answers in the House of Lords and the House of Commons on May 10, over 19,000 had then been issued and 7000 had been either found to be unsatisfactory or require repair. Again according to *Hansard,* at that time some 41,000 had been manufactured; what has happened to the odd 14,000 of this model called mark I is, as yet, unknown. It is almost certain that the whole of the first issue will eventually find their way to the scrap-heap because so many recipients are having to return them frequently for repairs.

We are also told, in *Hansard,* that an order for 100,000 of the new type called mark II has been placed. Some of the recipients are already complaining that this model, which is of the magnetic type, is not as powerful as the previous crystal type; and according to one hospital technician, quite a number of the earpieces have developed a fault within a short time of issue.

To supplement the present very inadequate service I submit that, after competent medical examination, the hard-of-hearing be allowed the alternative of a grant of, say, £10 towards the cost of approved commercial aid. These are guaranteed for one year; so that, for the first year, all those choosing this method would not be a liability on the National Health Service. For the following four years any repairs up to, say, a limit of £3 per year should be paid for by the service. Then, at the end of five years from the date of the first grant, a further grant should be allowed. Added to this there is also the cost of batteries; these are free to users of the medresco, and an equitable amount should be allowed to those using a commercial hearing-aid.

The Ministry of Health have, so far, maintained that any system of grants would not be an economical proposition. Unfortunately they do not give any figures regarding the cost of medresco, including the cost of repeated repairs, so that it is impossible to make any comparison.

As you reiterate, careful training in the use of a hearing-aid is essential with any type of aid; unfortunately this training has not so far been given. Experienced users of hearing-aids are prepared to u this task and it is to be hoped that the Ministry of will do something about this very important side service.

GRADING AND DEGRADING

Sir,—In the House of Commons recently, to a question on the grading of hospital medical the Minister of Health said:

> "It is wrong to speak of demoting. This is time that grading has been done; therefore there no demoting from a superior to an inferior grade."[1]

The Minister's statement, however, is not quite co because the local authorities' system of grading medical staff was in existence before the National Service; and (2) because the N.H.S. gradings —some say *intend*—definitely to demote medical tendents.

In what were recently local-authority hospit today constitute the majority of hospitals in the the classification of hospital medical staff in use contained the well-known grades of medical tendent, senior medical officers, and junior officers. In the Minister's classification, as pu in the Terms and Conditions of Service, the authority grades of senior medical officer and medical officer reappear as "senior hospital officer" and "junior hospital medical officer"; the medical-superintendent grade, which, correspon might have appeared as "chief hospital medical o is not represented as a separate and definite instead, medical superintendents are to be r in a variety of ways—namely, as consultant, or S.H or J.H.M.O.; or, perhaps, as part-time-consultant time-secretary, or part-time-S.H.M.O.-part-time-sec or even as part-time-consultant-part-time secretary, or part-time-S.H.M.O.-part-time-assistant tary; or, quite possibly, indeed, very likely, as time-J.H.M.O.-part-time-assistant-secretary: a sad fusion of terms arising out of a sadder conf ideas concerning the functions of these local-a medical officers.

Accordingly, a medical superintendent may himself graded as S.H.M.O.—and already many superintendents have been so graded—which, if it anything at all, means a definite demoting: for w before the grading, he was the chief medical o his hospital, he is now one of its senior medical and, it may be, lower in hospital status and in scale than his own deputy or one of his assistant m officers who has been graded as a consultant.

To maintain, therefore, that no demotings occurred, nor can occur, is to declare oneself, to say least, as strangely oblivious of existing facts and c happenings.

The Minister's classification appears to be the of an attempt to fuse two ideally different syste grading hospital medical staff—namely, the volun hospital system, based on the efficiency of counse the local-authority system, founded on the sufficie control. On examination, however, the new classifi is discovered to be not so much a fusion as a confu these two systems.

Yet, counsel and control are not incompatible it should be possible to achieve a satisfactory syn

The primary elements in the voluntary-hospital are consultants, specialists, and registrars; corresp units in the local-authority system are medical su

Obituary

HENRY HORSMAN McNABB

M.D. MANC.

Mr. H. H. McNabb, consulting surgeon to the Royal Eye Hospital, Manchester, died on July 28 at the age of 74. Born in Bolton, Lancashire, he graduated from the Manchester medical school in 1898. After a resident appointment at Monsall Fever Hospital, he became junior house-surgeon at the Manchester Eye Hospital, and he remained there on the resident staff for about four years. He was then appointed honorary assistant surgeon, and in due course honorary surgeon. In 1940, when he retired to the consulting staff, the board of management paid high tribute to his long service, and gave him freedom of the hospital beds for his patients.

T. M. B., a colleague of forty years' standing, writes : " I have never seen a finer technician in the art of ophthalmic surgery than Harry McNabb. He had beautifully dextrous hands which he could turn to operate in any position, and to any experienced ophthalmic surgeon it was an eye-opener to watch the skill with which he performed the most difficult intraocular operations. His colleagues, who are always close critics of a fellow surgeon, never disagreed that he was the premier operator of his period, and his many visitors from home and Continental clinics always paid enthusiastic tribute to his skill. His clinical sense was high : there has always been a tradition at the Manchester Royal Eye Hospital that any difficult case should receive the opinion of all members of the staff, and his view was much valued on these occasions.

" Occasionally he wrote in ophthalmic journals, but he was never a prolific writer, because, I think, he rather disliked any form of publicity. He always attended meetings of the Oxford Ophthalmological Congress, enjoying the discussions and perhaps even more the universal comradeship. He always took the greatest interest in the North of England Ophthalmological Society, of which he was an original member, and he became president in 1927.

" In his younger days, McNabb was a keen cricketer, being a useful batsman, and a good spin bowler. He was a member of the Manchester Racquets Club, and he also played tennis. In his own house, where he entertained many distinguished English and foreign ophthalmic surgeons, he was a delightful host. For some 20 years he had borne intermittent ill health with great fortitude, never complaining, and continuing his work almost to the last. A man without enemies, he will always be remembered by his friends as one truly kind of heart."

Mr. McNabb married in 1915 Miss Bywater. They had two sons, the elder of whom died young. His younger son is now an officer in a Scots regiment.

RALPH PEMBERTON

M.D. PENN., F.A.C.P.

Dr. Ralph Pemberton, professor of medicine at the graduate school of medicine of the University of Pennsylvania, had been president of the International League against Rheumatism since 1938, and it was a great disappointment to his fellow members that illness prevented him from attending the congress held in New York this summer. They heard with regret of his death on June 17 at the age of 72.

Pemberton was born in Philadelphia and graduated in medicine at the University of Pennsylvania in 1904. For the next four years he held internships at the Children's Hospital, the Pennsylvania Hospital, and the Philadelphia General Hospital. During these early appointments his interest in arthritis was aroused. The award of a Woodward fellowship in 1908 enabled him to study the dynamic pathology—as he termed it—of this disease : working with J. E. Sweet at the Pepper laboratory he investigated the inhibition of pancreatic activity by extracts of suprarenal and pituitary glands. Two years of postgraduate study at Berlin and Strasbourg further widened his experience, and when, after the 1914–18 war, during which he served as a major in the Medical largely negative the value of this innovation. In the case of inpatients, there seems to be no good reason for not using 24-hour collections if one wishes to record the 24-hour output.

The objections mentioned above may or may not hold good; on an entirely different basis, however, is the now very considerable evidence, from widely differing sources, that pregnanediol excretion, even when measured in terms of 24-hour outputs, can vary to such an extent as to reduce the clinical value of its measurement to a low level *except in special circumstances*. As I pointed out at the Congress of Obstetrics and Gynæcology, it appeared improbable that this state of affairs could be ascribed entirely to technical inadequacies, while at the same time there were no solid grounds for believing that pregnanediol excretion at all closely paralleled the production of progesterone (as had been shown most convincingly by Professor Marrian in his paper at the congress). I would reiterate now, what I suggested then, that a simple direct method of estimating the blood-progesterone would surely supply evidence of much more clinical value than could ever be expected from the pregnanediol excretion in the urine.

Obstetric Hospital, University College Hospital, London, W.C.1. G. I. M. SWYER.

PREVENTION OF BURNS AND SCALDS

SIR,—I read with interest the paper by Dr. Leonard Colebrook (July 30), which has had considerable publicity, including a leading article in the *Manchester Guardian*. I was surprised to find that it makes no mention of the activities of the professional fire brigades in encouraging fire-protection methods in the design of domestic appliances and better appreciation of fire prevention amongst members of the public.

Under the Fire Services Act, 1947, every fire brigade is *responsible for giving, when requested, advice in* respect of buildings and other property as to fire prevention, restricting the spread of fire, and means of escape in case of fire. Many fire brigades are actively concerned in carrying out propaganda and publicity towards this end, and I should like to congratulate Dr. Colebrook and your journal on publishing this article. We hope that, together with the efforts of the professional fire brigades, it will bring home to the public the constant source of danger which exists in every home and the number of avoidable deaths which are caused year after year through neglect to take reasonable precautions.

Fairfield Street,
Manchester, 1.

K. N. HOARE
Chief Officer,
City of Manchester Fire Brigade.

TESTICULAR PAIN

SIR,—Dr. MacDougall's account of the somatic nerve-supply to the testis is accurate; it strictly agrees with Gray's *Anatomy*. The visceral nerve-supply is not absolutely agreed on by all anatomists. In so far as he includes the renal and aortic plexuses, and therefore additional spinal segments, he merely argues my point with greater eloquence than I do. For my point is that testicular pain cannot be localised to a single invariable spot (point B, fig. 3 of Mr. Brown's article), whether its path be along visceral or somatic or both sets of nerves.

As he says, the tunica vaginalis is presumably innervated from the overlying somatic nerves. My own view is that the ilio-inguinal nerve is responsible most of all, because its course betrays its elongation as the tunica vaginalis descends into the scrotum; also, pain is not usually referred along the perineal nerves. What Mr. Brown actually calls "tunica vaginalis pain"—i.e., the testicular pain of the intact body—Dr. MacDougall would therefore assign to all the scrotal nerves. In this he unwittingly and fundamentally differs from the view he set out to defend—namely, that the genital nerve alone is wholly responsible.

As pointed out before, stimulation of the femoral nerve at the point where the ureter cr cannot possibly explain the descending nature of pain any more than a station-master at Newca see all the Flying Scotsman's movements between and Edinburgh. Testicular retraction in calculus o tion by no means refutes this. The motor are stimulated reflexly, not directly; so it is to adduce testicular retraction as evidence of nerve stimulation.

East Barnet, Herts. FELIX E. W

POLIOMYELITIS OR LEPTOSPIROSIS?

SIR,—It is said that many cases of anterior myelitis may be expected this autumn. Hence we should be noted that the meningeal form of lept closely resembles mild poliomyelitis without Infections with *Leptospira icterohæmorrhagiæ* *canicola* are being recognised with increasing in this country, and many of these cases occur autumn.

The possibility that the meningitis may be *L. icterohæmorrhagiæ* should be considered if the has bathed in stagnant fresh-water, or if he is to come into contact, at work, with water which contaminated with rat urine. Contact with a would suggest the chance of infection with *L. c* The diagnosis can most easily be confirmed by the patient's serum for the presence of lept anti-bodies, which first appear about the of illness. Unfortunately, laboratory diagnosis usually practicable in the earliest stages of the dise

Other forms of meningitis may resemble poliom and bacteriological examination of blood or spinal fluid can detect the responsible micro-org or virus in many instances. As regards poliomy the diagnosis by laboratory methods cannot al assured in mild cases.

If leptospiral meningitis is the correct diagnos prognosis is improved, because death and perm disability are almost unknown. In addition, thi nosis removes anxiety about poliomyelitis deve in the patient's neighbourhood.

MALE TOADS IN PREGNANCY TESTS

SIR,—As the letter from Professor Bach and Dr. S (July 30) may prove misleading to those who di see the previous letter by Bach et al,[1] we should to point out that their series of 610 tests was app performed on *Rana esculenta*, not on *Bufo bufo*. only reference to the latter species was the statement "though we have found it [bufo] equally satisfa for the purpose . . . we have used the edible frog, *esculenta*."

Bach and Szmuk say further that "*R. esculent* proved more sensitive, giving a positive result with 10–12 units of gonadotrophic hormone." This is from Bach et al.[1] who did not mention any gonadotr level for *B. bufo*. Our finding,[2] that this specie give a positive response with 8 I.U. of chorionic trophin, has since been confirmed, but the sul under further investigation. Bach et al. quoted Mainini's results obtained on the giant South Ame *Bufo arenarum* Hensel, where the threshold was 40 units. One would expect the much sma *esculenta* to have a lower threshold than this.

MEMORIAL TO ROBERT WILLAN

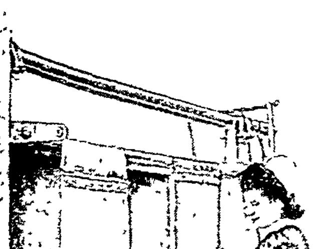
day, Aug. 12, a tablet is being affixed by the London ouncil to No. 10, Bloomsbury Square, in memory Robert Willan (1757-1812). Willan was appointed to the public dispensary opened in Carey Street, coln's Inn, in 1783. In his *Description and Treat- utaneous Diseases*, published in parts between 1797 8, he established a nomenclature of skin diseases still more or less in use today. He lived at No. 10 0 until shortly before his death.

LIGHTING OF BUILDINGS

luminating Engineering Society's *Code for the Lighting ing Interiors* is a set of rules and recommendations both natural and artificial lighting for all types of s. The society, whose membership includes repre- es of the lighting industry and users of light, says recommended values of illumination are in general han those recommended in some other countries; t this country we are not yet satisfied that there is antage to be gained by raising levels above a certain The most significant change in the 1949 edition ode[1] is that the illumination charts are now printed r. A useful addition is the list of British Standard ations on illumination and lighting fittings.

A CRANE FOR LIFTING PATIENTS

VICE which enables one nurse to lift and turn a heavy or a patient in a heavy plaster-cast, has been designed C. H. Cullen, an engineer. The apparatus consists ter frame of 'Duralumin,' consisting of two uprights ing a crossbar to which an oblong frame is slung bed belting. The belting passes over pulleys at each d leads to a winch, on one of the uprights, operated by a crank-handle. By means of this winch the frame can be raised or lowered. From the frame depend two broad canvas slings which can be passed under the patient and secured; and these slings pass over parallel rollers fitted to either side of the frame. The apparatus, which can be assembled in ten minutes, stands over the bed with one upright at the head and one at the foot. The slings are threaded round the patient and fastened over the parallel rollers of the frame. The winch can then be operated by a nurse, and when the patient is clear of the bed he can be d easily by pulling one of the canvas slings so that it round over the rollers. If a patient in a plaster-cast be lifted the distance between the parallel rollers can be ished so that the plaster is well gripped by the slings the patient is half turned, and there is no danger of rolling over suddenly. The device is said to make easy, and comfortable the moving and turning of helpless and heavy patients. It should be specially useful where nursing staff is scarce.



The crane in action.

The Cullen Crane has been patented and is made by Cecil H. Cullen & Son, Langford, Bristol.

† Distinction.

Dr. Robert Knox has been appointed to the chair of bacteriology at Guy's Hospital medical school.

Dr. Knox took the Conjoint qualification from St. Bartholomew's Hospital in 1932 and his M.B. Lond. the same year. Two years later he proceeded to his M.D. and the M.R.C.P. After holding house-appointments and a chief assistantship at Barts he became demonstrator in pathology at the University of Cambridge, where he took his M.A. in 1935. Later he joined the staff of the Imperial Cancer Research Fund and he worked at the Mill Hill laboratories till he was appointed to his present post of director of the public health laboratory at Oxford under the Medical Research Council. In 1945 the University of Oxford conferred on him the degree of M.A. Dr. Knox has published papers on bacterial tetrathionase and on the effect of penicillin on cultures in liquid and solid media.

The title of professor of bacteriology has been conferred on Dr. F. R. Selbie in respect of the post held by him at Middlesex Hospital medical school.

Dr. Selb [illegible] at the University of Aberdeen with first-class [illegible] house-appointments in Aberdeen before he [illegible] Imperial Cancer Research Fund in London. In 1932 he took his M.D. with highest honours. In 1939 he became assistant pathologist at the Bland-Sutton Institute at the Middlesex Hospital, and two years ago he was appointed to a readership in bacteriology at the school.

University of Manchester

Mr. W. Sayle-Creer has been appointed honorary clinical lecturer in orthopædic surgery.

An annual prize in pathology has been established in memory of the late Dr. William Susman, lecturer in morbid anatomy and histology from 1926 to 1948. The first award will be made in 1950.

British Society of Periodontology

This society has lately been formed to promote the study of periodontology, and Dr. E. W. Fish has been elected the first president. The society will meet during the winter months, and papers, communications, or demonstrations will be presented. The initial membership is about 40. The hon. secretary may be addressed at the Institute of Dental Surgery, Eastman Dental Clinic, Gray's Inn Road, London, W.C.1.

Establishments of Medical and Dental Staff

The Minister of Health has asked the regional hospital boards and the boards of governors of teaching hospitals to tell him the number and type of posts which they have determined as the establishment of their hospital services for the immediate future. If a different establishment is contemplated within the next two years, the contemplated new figure is also to be stated. The establishments, the Ministry points out, are not subject to its approval, but it would be helpful to the Minister to know what is being done by boards and committees.

---

[1] btainable from the society at 32, Victoria Street, London, S.W.1. Pp. 28. 2s. 6d., post free.

Corps, he once more settled in Philadelphia, he quickly won recognition. Soon afterwards he set up his famous arthritis clinic at the Abington Memorial Hospital. He also joined the staffs of the Chester County Hospital and the Presbyterian Hospital.

His *Arthritis and Rheumatoid Conditions*, which first appeared in 1930, marked an important advance in the approach to arthritis, for his studies of the disturbances of normal physiology in the early stages of this group of diseases did much to remove the confusion surrounding them and to put their treatment on a scientific basis. His *Medical and Orthopædic Management of Chronic Arthritis* (with R. B. Osgood) appeared four years later. A former chairman of the American Campaign for the Control of Rheumatism, Pemberton was in 1946 awarded the gold key of the American Congress of Physical Medicine in recognition of his work on arthritis. But his reputation was transatlantic and his honorary fellowship of our Royal Society of Medicine was only one sign of the European esteem he had gained.

Appointments

BLACK, M. D., M.B. Glasg., F.R.C.S.E., F.R.F.P.S., M.R.C.O.G.: asst. obstetrician and gynæcologist, Lanark County area.

ERSKINE, J. P. O., M.B. Glasg., F.R.F.P.S., M.R.C.O.G.: *chief obstetrician and gynæcologist, Dunbarton County area.*

HOLLAND, C. B., D.S.C., M.B. Manc., D.A.: consultant anæsthetist, Ipswich area.

TENNENT, R. A., M.B.E., M.B. Glasg., M.R.C.O.G.: chief obstetrician and gynæcologist, Lanark County area.

King Edward VII Convalescent Home for Officers, Osborne:

Civil Consulting Staff:

PORRITT, A. E., C.B.E., M.A., M.CH. Oxfd, F.R.C.S.
ROSS, Sir JAMES, M.S. Lond., F.R.C.S.

Births, Marriages, and Deaths

BIRTHS

ALLEN.—On July 27, in London, the wife of Dr. S. J. Allen—a daughter.

ASHWORTH.—On July 31, the wife of Dr. H. W. Ashworth—a daughter.

CONWAY.—On July 19, in Glasgow, to Dr. Lilian Conway (*née* Donald), wife of Dr. Hugh Conway—a daughter.

BEILBY.—On July 29, at Hoddesdon, Herts, the wife of Dr. F. G. Beilby—a son.

DIGGLES.—On Aug. 2, at Walkden, the wife of Dr. H. Diggles—a son.

EBERLE.—On July 30, the wife of Dr. A. J. F. Eberle—a daughter.

FAIRBAIRN.—On Aug. 7, in London, the wife of Dr. A. S. Fairbairn—a daughter.

GEMMELL.—On Aug. 1, at Prestwick, the wife of Dr. A. R. Gemmell—a son.

GIMSON.—On Aug. 3, at Aylesbury, the wife of Dr. Peter Gimson—a daughter.

JEREMY.—On July 27, the wife of Dr. W. H. R. Jeremy—a daughter.

LODGE.—On Aug. 2, at Wisbech, the wife of Dr. F. E. Lodge—a son.

RAMSAY.—On July 30, at Londonderry, the wife of Dr. R. H. Ramsay—a daughter.

* STERN.—On June 12, in Cape Town, to Dr. Edna Stern (*née* Bowman), wife of Dr. Alfred Stern—a son.

SULLIVAN.—On Aug. 4, the wife of Dr. B. Sullivan—a daughter.

THOMPSON.—On July 25, the wife of Dr. P. H. Thompson—a son.

WELLS.—On July 31, at Wimbledon, the wife of Mr. B. W. Wells, F.R.C.S.—a daughter.

WHITEHEAD.—On Aug. 2, at Salisbury, the wife of Dr. B. L. Whitehead—a daughter.

* Amended notice.

MARRIAGES

EASON—TOWLER.—On Aug. 6, at Croydon, Thomas John Eason, F.R.C.S., to Ruth Willand Towler, M.B.

EVANS—MITCHELL.—On July 31, in London, Carlton John Evans, M.R.C.S., to Alexa Mitchell, M.R.C.S.

DEATHS

BUTLER.—On July 29, Hedley Ormonde Butler, B.A., M.B. Camb.

CHARLES.—On Aug. 2, at Bournemouth, Rhys Pendrill Charles, T.D., M.D. Berne, F.R.I.C.

HOPKINSON.—On July 31, at Cambridge, Albert Hopkinson, M.A., M.B. Camb., B.SC. Manc., aged 85.

LYLE.—On Aug. 2, in Belfast, William Lyle, M.B. R.U.I., aged 76.

MCNABB.—On July 28, Harry Horsman McNabb, M.D. Manc., aged 74.

PALMER.—On July 28, at Accra, Gold Coast, Ralph Winnall Palmer, M.R.C.S., aged 35.

WILSON.—On July 30, in Birmingham, Theodore Stacey Wilson, M.D., B.SC. Edin., F.R.C.P., aged 88.

Notes and News

BRITISH SOCIETY OF NEUROLOGICAL S

THIS society held its 40th meeting in London, on and 23, under the presidency of Prof. Lambert Rog ings were held at the National Hospital, Queen Sq at University College Hospital medical school. T large attendance which included visitors from th States, South Africa, Australia, and Europe. Dr. Sachs, of St. Louis, was made an honorary member.

The research unit from Queen Square described t neurophysiological studies. Dr. Paul Bucy, of spoke on the surgical treatment of involuntary a subject of interest and importance at present in the extravagant and seemingly unfounded claims the daily press for cortical excision operations. disease is incurable by operation, and the most that hoped for is the abolition or diminution of tremor. Dr said that both his own experience and that of American neurosurgeons had shown that involuntary ments cannot be stopped without excising the mo which naturally produces profound weakness or the affected limb. Dr. R. A. H. Krynauw of Johann an account of his experiences of removing the hemisphere in hemiplegic epileptic children.

At the society's dinner Dr. Sachs gave some reminiscences of Sir Victor Horsley, under whom studied; and Dr. Francis Grant, of Philadelphia, about the organisation and present-day trends of ne in America.

COLLECTIONS OF MICRO-ORGANISMS PROTOZOA

IN connexion with the British Commonwealth Conference, 1946, a specialist conference was held on collections of micro-organisms; and this conference mended that a directory of the important culture co of the Commonwealth should be prepared. A di the collections maintained in the United Kingdom Crown Colonies has now been compiled by the United national committee of the British Commonwealth C of Micro-Organisms organisations; and later the gen species in the various collections are to be listed directory is obtainable, without charge, from the sec the United Kingdom committee, 38, Old Queen Street, S.W.1.

A catalogue of the arthropods, helminths, moll protozoa of human and veterinary interest that tained at institutes in the United Kingdom has been by the Laboratory Animals Bureau, Royal Veterina Royal College Street, London, N.W.1. The cat be had, gratis, on application to the director of the

SWEET RATIONING

WHEN sweet rationing is reintroduced on Aug. 14 patients will still be able to obtain, without su personal points, packets of glucose tablets for use in e These tablets are prepared specially for medicinal pharmacists are asked to reserve them for custo they know to be diabetics.

By the terms of the new Ministry of Food Order, will not be able to have glucose barley-sugar ordered for on E.C.10s. A doctor may, if he wishes, give a pati "approved order" (not being an E.C.10) which may be to a chemist only, and the barley sugar may then be o on payment by the patient.

A LIGHTWEIGHT RESPIRATOR

THERE is no longer any doubt that lives may be in the acute stage of poliomyelitis by the prompt u respirator. The great variety and ingenuity of the d constructed for this purpose were indicated by Dr. Blackwell in her paper of July 16. She mentione compact "cuirass" respirator invented by Professor B of Melbourne, consisting of a rigid jacket enclosing the t The interior of the jacket is made airtight by the rubber collars round the lower edge and round the o for the arms and neck. Rhythmic compression of the is attained by alternately raising and lowering the p inside the jacket with a motor-driven or manual According to British United Press, another respirator

OPHYLACTIC SULPHANILAMIDE IN RHEUMATIC FEVER

REVIEW OF 548 CASES

YDNEY D. RUBBO MARGARET C. HOLMES

and Children's Hospital, Melbourne

UGH sulphonamide therapy for reducing the nce-rate in rheumatic fever has been well estab- by numerous American workers, no report has ublished from British or Australian sources except son's (1945). Further, in America, Wilson and lez (1944) carefully analysed statistically the published by five other groups of workers and ded that the final assessment of preventive chemo- y must be deferred, because the recurrence-rate ot significantly lower in patients receiving chemo- y than in controls. More recently Wilson (1947) ed this view, and Perry (1948) remarked that the of prophylactic sulphonamides had not been sive.

INVESTIGATION

value of sulphanilamide as a prophylactic to reduce ecurrence-rate of rheumatic fever has been under igation at the Children's Hospital, Melbourne, 1944. The material presented here fulfils the a which Wilson considered essential for an adequate tistical analysis. The patients selected for treat- were chosen without bias, the same clinical criteria ised for the diagnosis of recurrence, and the results calculated according to the method used by Frost in his studies on pulmonary tuberculosis. The groups of patients were large enough to exclude ement of chance affecting the results. In fact, the number of 1536 person-years included in both our ol and sulphanilamide groups is the largest yet ted by a single team of workers.

all daily doses of sulphanilamide have been given nuously to 211 children aged 4–14 years for 565 n-years, and over the same period 337 children have observed as controls for 971 person-years. The children received 0·5 g. of sulphanilamide night morning, except those weighing less than 42 lb., were given 0·25 g. night and morning. Since in ourne there is no pronounced seasonal incidence of natic fever, continuous prophylaxis was maintained ghout each year. Toxic manifestations due to anilamide were carefully sought by examining the ren weekly for the first six weeks and thereafter at eek intervals, when white-cell counts were performed the general progress of the children was noted. In ew cases where abnormal findings were obtained a lete blood examination was made.

ood-sulphanilamide levels were determined in some nts; but, since it was established that a daily ge of 1 g. maintained an average blood-level of ng. per 100 ml., these routine tests were discontinued.

urrence was diagnosed on the appearance of one or major manifestations—polyarthritis, carditis, and ea—necessitating complete rest in bed and admission ospital. A parent's history of suggestive symptoms he absence of supporting evidence on clinical nination was not accepted as a recurrence.

e bacteriological work consisted of the isolation of olytic streptococci by anaerobic culture from ated throat swabs (tonsillar and postpharyngeal s), serological grouping, and sulphanilamide- itivity tests on the organisms isolated. The hæmolytic streptococci were isolated by plating out throat swabs on 8% horse-blood-agar containing 1 in 500,000 gentian violet and incubating anaerobically for 18–24 hours at 37°C. It was found early in this work that anaerobic culture significantly increased the recovery-rate of hæmolytic streptococci, a finding consistent with the results of Fry (1933) and Jones et al. (1941). The successful isolation of these organisms from identical swabs by aerobic and anaerobic techniques is compared in table I.

In most cases where strains were isolated from the anaerobic plates only a few colonies were present and the profuse growth of other organisms on the aerobic plates obscured the sparse growth of the hæmolytic streptococci. Thus anaerobic incubation, besides improving the hæmolysis, retards the growth of contaminant organisms and so provides a more sensitive method of detection, particularly when only a few streptococci are present.

TABLE I—COMPARISON OF AEROBIC AND ANAEROBIC METHODS FOR PRIMARY ISOLATION OF HÆMOLYTIC STREPTOCOCCI

Successful isolation	Group A		Groups B, C, and G	
	Aerobic	Anaerobic	Aerobic	Anaerobic
No. positive . .	121 (*63%*)	192 (*100%*)	58 (*77%*)	75 (*100%*)

The organisms were grouped serologically by Fuller's (1938) method of polysaccharide extraction and antisera of Lancefield's groups A, B, C, and G. Sulphanilamide-sensitivity tests were made according to the technique of Harper and Cawston (1945) with concentrations of 2 and 10 mg. of sulphanilamide per 100 ml. of the medium.

Recurrence-rate

Before discussing the influence of chemoprophylaxis on recurrence-rate it is essential to describe briefly the methods of matching the treated and control groups of patients. The following factors were investigated:

(1) The age-distribution in person-years for the two groups is shown in fig. 1, which shows that, except for those aged 13, the age-distribution did not vary more than 5%, and in this respect the patients may be regarded as comparable.

(2) It is well known that the likelihood of recurrence decreases with the increase of time following a major episode, either a first attack or a recurrence. Hence it was of first importance to consider the time-interval between the start of prophylactic sulphanilamide therapy and the occurrence of the last major episode. Fig. 2 shows the time-interval separating major episodes, calculated from an analysis of 162 recurrences in children attending our clinic over 1253 person-years. It will be seen that the tendency to recur is greatest during the first and second years following a major episode, and that the recurrence-rate thereafter is constant, but lower, during the third and fourth years. The increased recurrence-rate during the second year, which differs from

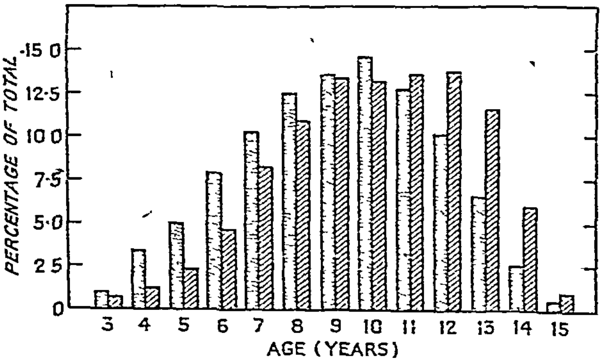

Fig. 1—Age-distribution in person-years for sulphanilamide group (hatched columns) comprising 565 person-years and for controls (stippled columns) comprising 971 person-years.

Royal Institute of Public Health and Hygiene

Dr. George Graham has been appointed Harben lecturer for 1949. He will deliver his lectures on Jan. 23, 24, and 25, 1950, and he has chosen diabetes as his subject.

Rector of Malta University's Visit

Dr. J. A. Manché, rector of the University of Malta, is spending three weeks in this country visiting laboratories, medical schools, and teaching hospitals to see teaching methods.

Regional Neurosurgeon

Mr. J. M. Small, assistant neurosurgeon in the United Birmingham Hospitals, has be [illegible] -charge of the Birmingham regional [illegible]

International Union of Nutritional Sciences

In connexion with meetings of the committee of this body, to be held in Copenhagen on Sept. 12 and 14, it has been arranged to hold some scientific sessions and visits to institutes of nutritional interest in the neighbourhood of Copenhagen between Monday and Friday, Sept. 12 and 16. It is thought that these may be of interest to a wider circle of nutritional workers. Further information may be had from Prof. H. Dam, biology department, Polytechnic Institute, Østervoldgade 10 L II, Copenhagen, Denmark, or Dr. Torben K. With, Rigshospitalet, Copenhagen, Denmark.

Sprayed Pears

Examinations made by medical officers of health have shown that a small proportion of the pears now arriving from Italy still retain a slight trace of an antiparasitic spray. The spray can easily be removed by wiping with a cloth, and the health authorities are examining all the pears now arriving to ensure that this is done where necessary before the fruit is offered to the public. The Italian commercial authorities have taken steps to prevent further consignments of affected fruit from being exported.

Exhibition for the Rheumatic

The British Rheumatic Association is holding an exhibition from Sept. 27 to 30, at the Town Hall, Chelsea, which will include a display of wheel chairs and a demonstration of the work of the disablement section of the Ministry of Labour, of "Remploy" and of voluntary organisations in training and work for the disabled, and of aids and appliances for home-therapy and physiotherapy. A conference, on the welfare of the rheumatic patient and the interests of the handicapped rheumatic, will take place concurrently with the exhibition. Tickets for the conference may be had from 5, Tite Street, London, S.W.3.

Medical Sickness, Annuity and Life Assurance Society

Speaking at the annual general meeting on July 25, Mr. R. J. McNeill Love, the chairman of the directors, said that since the National Health Service started the society had been able to help many members, both by advice on questions which arose out of the superannuation regulations and by devising new policies to meet the altered conditions. A private limited company, the Medical Sickness Finance Corporation, Ltd., had now been incorporated to offer doctors hire-purchase facilities for cars or equipment. The corporation was operating from the society's offices.

New life assurances, he continued, effected during the year amounted to over £771,000, a record in the history of the society; while life assurance claims were less by £20,000. The total funds now exceeded £4 million.

Central Council for Health Education

At the 22nd annual general meeting, held on July 28, Dr. E. K. Macdonald, the chairman, pointed out that despite the reduction in the grant from the Ministry of Health the council had maintained its equilibrium and introduced several promising developments. During the year three series of short refresher courses had been held at 12 university centres in England, Wales, and Northern Ireland. Three-quarters of all local health authorities in England, Wales, and Northern Ireland were using the new exhibition service which provided free portable stands with regular changes of material. The council was also planning a series of leaflets dealing with specific disorders, which general practitioners would be able to hand to patients at consultation. These leaflets would contain information about diet, &c., which would supplement the physician's verbal instructions, and which the patient could keep for reference. The scheme would be operated in conjunction with local authorities.

Royal Appointments

The King has appointed the following to his household: Lord Horder, extra physician; Sir Walton, extra surgeon; Sir Morton Smart, extra surgeon.

Three Years of Family Allowances

The Family Allowances Scheme was started ago on Aug. 6, 1946. Now about 2,941,000 families of more children are receiving allowances at a cost of £60 a year. Of the families receiving allowances 1,850,000 two children, 688,000 contain three, 247,000 co and 156,000 contain five or more. The family largest allowance of £3 5s. a week consists of fourteen within the age-limits.

Institute of V.D. Technicians

At the inaugural conference of this institute, Manchester on July 23, Mr. R. A. Henderson, secretary, said that though venereal-disease were performing a very exacting and highly of great social and national importance, their yet been defined. The primary function of the ins be the recruitment and training of male Si nurses for this work, and the setting of examinations For recognition the institute must gain the venereologists throughout the country and that Medical Society for the Study of Venereal Di it would not merit such approval unless it set the possible standard. When these aims and objects accomplished, V.D. technicians could go to the authority and ask for the technical status which the of their duties warranted.

Special Glasses for Colour-blind Drivers

A new type of three-colour spectacle lens, desi pally to help the colour-blind motorist distinguish traffic signals, has been devised at the U.S. Air Force of Aviation Medicine. The new lenses, of which the halves are clear and the upper halves coloured green enable the driver to tell whether the green light or light is showing. The glasses (says British United based on the fact that, seen through a red filter, as almost black, and red or yellow almost white; green filter, red looks black and green almost white moving his eyes slightly to the right and the left the will be able to tell which light is showing, while the lower half of each lens will prevent any int normal vision for other purposes.

Water and Sewerage in Rural Areas

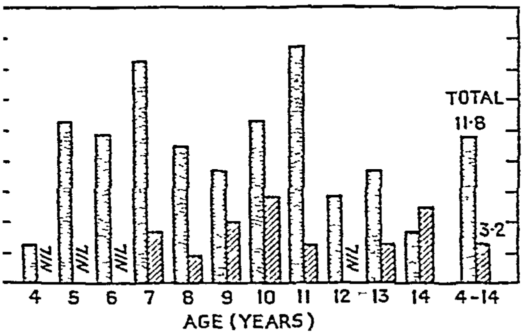
A month ago the National Federation of Women's wrote to every Member of the House of Commons House of Lords enclosing a copy of the water and survey it published in 1944. On July 25 a received by the Minister of Health, spoke of the of improving the water-supplies to meet the of agriculture; and the disquieting lack of local authorities since the 1945 Water Act, in piped water-supplies in rural areas. They urged whole question should be given a very high place Government's programme; that small-scale schemes be grant-aided and approved to a greater extent than hi that material for water-supply works should be put Prime Minister's priority list; and that the Ministry of should speed up and simplify its procedure for dealing local-authority schemes. The Minister expressed wholly in sympathy with the deputation, and do all in his power to speed up the work now going connexion with water and sewerage schemes. He emphatic that he could not grant-aid local isolated but he was equally clear that small-scale local schemes up with bigger schemes were eligible for help.

Sir Lionel Whitby, regius professor of physic in University of Cambridge, will be visiting Canada and United States from the middle of August to the be of October.

Prof. J. C. Spence's address to the conference of Health on the Need for Understanding the Individual (L 1949, i, 535) has been reprinted as a booklet. It is o from the National Association of Mental Health, 39, Anne Street, London, W.1, price 3*d*.

and 5. Hence we cannot offer any explanation in terms of age-incidence, age at the first attack, gth of time between attacks. Jackson et al. whose results are also quoted in table III, noted comment an irregular periodicity in recurrence.

ly, we wish to draw attention to the significantly ecurrence-rate in Australian children compared at in New York (Wilson and Lubschez 1944). no personal experience of the environmental and ctors operating in New York we cannot profitably this difference. The recurrence-rate in our more closely parallels that in the children ng the University Hospital, Iowa (Jackson 947).



Recurrence-rates for different ages in sulphanilamide group ed columns) comprising 211 patients aged 4-14 years (565 person- and in controls (stippled columns) comprising 337 patients -14 years (971 person-years).

HÆMOLYTIC STREPTOCOCCAL CARRIER-RATE

ppears that rheumatic fever usually follows a ytic streptococcal infection, provided certain and environmental conditions are simultaneously t. The adoption of prophylactic sulphonamide y is based on this concept, and its success must be ed as further support of this view. Though our y object here was the clinical assessment of prophylaxis, it was thought desirable to determine ect on the hæmolytic streptococcal carrier-rate in tients over a period of about three years. Our s are recorded in two ways: (1) a general sion of the influence of prophylactic sulphanil- is obtained by comparing the number of positive es obtained in each group without taking into consideration the number of children involved or the number of swabs taken from each child; and (2) the hæmolytic streptococcal status of the patients from each group is assessed, based on only those children from whom eight or more swabs have been taken during the investigation. The calculations yield essentially the same results.

III—RECURRENCE-RATES IN CONTROL AND PROPHYLACTIC SULPHANILAMIDE GROUPS

No. of person-years		No. of recurrences		Recurrence-rate %		Recurrence-rate % reported by other workers	
Control	Sulphanil-amide	Control	Sulphanil-amide	Control	Sulphanil-amide	Wilson and Lubschez (1944)	Jackson et al. (1947)
8	3	0	0	0	0	—	—
33	6	1	0	3	0	23	0
48	13	6	0	13	0	24	6
76	26	9	0	12	0	32	0
100	47	18	2	18	4	34	2
121	61	13	1	11	2	31	11
132	75	12	4	9	5	26	5
141	74	19	5	13	7	28	8
124	77	23	2	19	3	25	15
97	78	7	0	7	0	18	11
64	69	6	2	9	3	15	7
27	36	1	2	4	6	—	6
971	565	115	18	11·8	3·2	25·0	7·7

l group: 337 patients comprising 971 person-years.
nilamide group: 211 patients comprising 565 person-years.

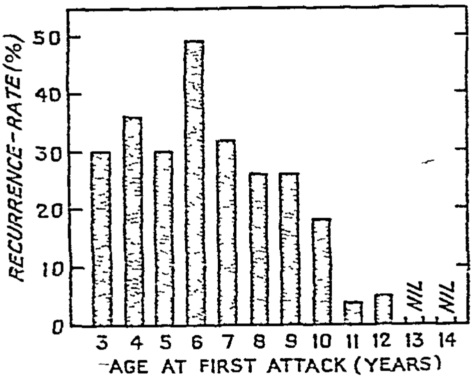


Fig. 6—Recurrence-rates in relation to age at first attack in 341 patients.

The recovery-rate of hæmolytic streptococci in the two groups (fig. 7) was as follows:

Hæmolytic streptococci	Positive Swabs (%) Controls (No. of swabs 2402)	Positive Swabs (%) Sulphanilamide group (No. of swabs 1856)
Group A	24·5	13·0
Group B	1·6	0·4
Group C	3·6	4·0
Group G	6·8	7·0

It will be noted that a considerable reduction in the rate of recovery of group-A streptococci was observed in the sulphanilamide group, compared with the controls.

It is noteworthy that where sulphanilamide significantly reduces the incidence of group-A hæmolytic streptococci it has no influence on groups C and G. In group G this discriminative effect can be attributed to the natural resistance of these strains, in that 62% isolated from the controls were resistant in vitro to 2 mg. of sulphanilamide per 100 ml. This contrasts with the sensitivity of group-A strains (fig. 9).

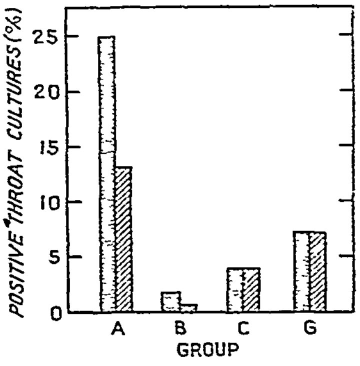

Fig. 7—Recovery-rate of hæmolytic streptococci from throats of rheumatic-fever patients: result of 1856 swabs for sulphanilamide group (hatched columns) and 2402 swabs from controls (stippled columns).

Of the children who had 8 or more throat swabs examined (table IV and fig. 8) there was a significant increase in the non-carriers of group-A streptococci in the sulphanilamide group. Further, the transient carrier state (arbitrarily defined here as that of a person from whom group-A streptococci has been detected in 1–3 swabs out of 8) was lower in the sulphanilamide group. Finally, the chronic or persistent carriers (4 or more positive swabs out of 8) differed by only 8% in favour of the treated patients—a figure which cannot be regarded as significant in that the difference might be attributed to chance with a probability of about 40%. However, the chance of recovery of streptococci is heavily weighted in favour of the treated patients, since more swabs were examined from these children.

On the evidence presented we conclude that prophylactic sulphanilamide therapy tends to counteract the colonisation of group-A hæmolytic streptococci, but this *the findings of Wilson and Lubschez (1944)*, can best be explained by the fact that our patients are kept in hospital for an average of 4·8 months after a major rheumatic episode and our time-intervals are calculated from the onset of the rheumatic attack. Thus the recurrence-rate in the first year does not cover 12 months but an average period of 7·2 months. Fig. 3 shows that 88% of our patients were put on sulphanilamide prophylaxis in the first and second years following the last major episode. On this evidence it is clear that most of the patients in the prophylactic group were studied while they were susceptible to recurrences.

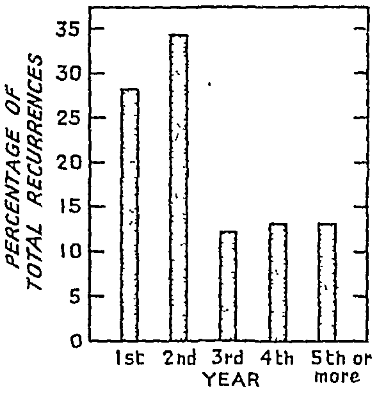

Fig. 2.—Times of recurrences of rheumatic fever (162 recurrences in 1253 person-years).

(3) It is stated (Cohn and Lingg 1943, Taran 1944) that the more severe the initial attack the greater is the tendency towards recurrence. We have tried to assess severity of the initial attack in our two groups by considering the cardiac status and the duration of complete rest in bed of our patients. The cardiac status was assessed clinically on the sleeping pulse-rate, cardiac enlargement, nature of cardiac murmurs, valvular dysfunction, and involvement of other cardiac structures. The duration of complete rest in bed merely reflected the severity of the carditis but was invaluable as a confirmatory index of cardiac involvement and as a measure of the severity of chorea in the absence of serious cardiac complications. In table II the two groups of children are compared on this basis, and it will be seen that a close agreement is obtained. We may note in passing that, though most of our patients had only mild attacks according to our classification, these were serious enough to require an average period of 4·3 months' detention in hospital. The recurrence-rates in our three classes of severity were as follows:

Severity of first attack	*No. of patients*	*No. recurring*
Mild	303	79 (26%)
Moderate or severe	41	10 (25%)

It will be seen that our findings show no significant difference in the tendency towards recurrence following a mild, a moderate, or a severe attack.

(4) In spite of consideration of the obvious factors which might explain any observed differences in the recurrence-rate in our two groups, it still might be said that less apparent factors had been inadvertently overlooked which collectively could invalidate our conclusions. For example, social environment, including the complex factors of home, school, district, and economic epidemiology, has a recognisable influence on recurrence-rate (Taran 1941). Instead of trying to measure social environment by some nebulous arithmetical or verbal yardstick, we preferred to determine the susceptibility to recurrence in our treated group by comparing the recurrence-rate of these patients before starting sulphanilamide therapy with that of the controls. Fig. 4 shows parallel and closely identical recurrence-rates in the two groups. In fact, the tendency towards recurrence was greater in the presulphanilamide patients than in the controls.

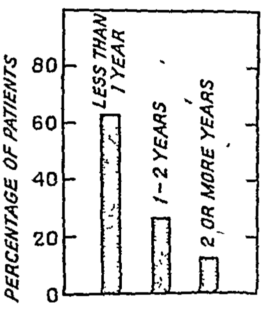

Fig. 3.—Times of start of prophylactic sulphanilamide therapy after an episode of rheumatic fever.

RESULTS

Having presented sufficient evidence to establish the close identity of our two groups, we now present our findings on the value of prophylactic sulph therapy. The results are recorded in table III fig. 5. It will be seen that the recurrence significantly less in the sulphanilamide group the controls. Combined results showed that for aged 4–14 years a recurrence-rate of 11·8% was o in the controls, whereas one of only 3·2% was o in the sulphanilamide group. When it is recalled these results are calculated from an analysis of recurrences in 971 person-years among the control 18 in 565 person-years among the sulphanilamide the statistical significance of our findings is ap Further, our results closely parallel the con reports of previous workers, which show r rates of 2·2% for the treated groups and 13·7% controls (Hench et al. 1948).

The recurrence-rates in children aged 14 years 6% in the sulphanilamide group and 4% in the co (table III). This difference is not significant and, had the dosage of sulphanilamide been incr accordance with the child's gain in weight, a favourable result might have been obtained.

TABLE II—COMPARISON OF SEVERITY OF FIRST A CONTROL AND SULPHANILAMIDE GROUPS

Severity of first attack	Average stay in hospital (months)	Control group (300 patients)	Sulp (176
Mild	4·3	87%	88%
Moderate ..	6·6	10%	11%
Severe ..	10·8	3%	3%

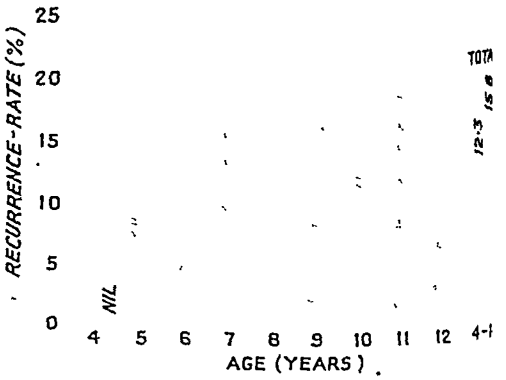

Fig. 4—Recurrence-rates for different ages in pre-sulphanilamid (hatched columns) comprising 183 patients aged 4-12 ye person-years) and in controls (stippled columns) compris patients aged 4-12 years (880 person-years).

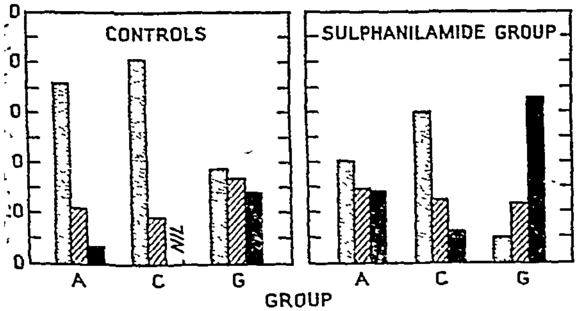
Another point worthy of comment is the irregularity in the recurrence-rates in each age This finding is quite different from that of Wilso Lubschez (1944), whose results are also includ table III. It will be noted that these workers, pr ably using the same method of calculation as w obtained a gradual and regular decrease in recu rate as age progressed from *7 to 13 years*, where figures show distinct peaks at 7, 10, and 11 years have carefully examined our data from different of view in an attempt to discover the reason for peaks and for the discrepancy from the general of results reported by Wilson and Lubschez. We found that the tendency towards recurrence is gr in patients having a first attack at the age of 6 yea diminishes as the age at the first attack advances. finding is illustrated in fig. 6.

Further, calculation of recurrence-rates for the di ages, based only on first recurrences and not on mu recurrences, showed the same peaks as indicat wabs were cultivated anaerobically, and from 1331 lytic streptococci were recovered. These organisms grouped serologically. This survey showed a d incidence in group-A streptococcal carrier-rate the treated patients, but the results were less itic than those obtained in the United States training centres during 1944 (United States Navy tment 1944). Further, carrier-rates for groups C and unaffected by prophylactic sulphanilamide therapy. two phenomena—recurrence-rate and group-A r-rate—thus exhibited a common decline under the nce of prophylactic sulphanilamide. This evidence ms the current concept that group-A hæmolytic ococci are ætiologically related to rheumatic fever, t must be emphasised that the presence of these isms in the throat is not per se a criterion of infec-

It is now generally agreed that a high (greater 150 units per ml. of serum) or rising antistreptolysin titre is a more valuable indication of streptococcal ion than is isolation of the organism from a throat . (Commission on Acute Respiratory Diseases , Keith and Carpenter 1946). It was impossible e present study to carry out mass antistreptolysin ions, and we have restricted the use of this test ute rheumatic attacks. Accordingly, the reduced ence of hæmolytic streptococcal carrier-rate can be regarded as suggestive evidence of a corresponding ction in streptococcal infections.

spite of these favourable impressions two possible tions to prophylactic sulphonamide therapy can dvanced. The first deals with the toxic reactions to the drug, and the second with the development of stant organisms.



9—Resistance of hæmolytic streptococci to sulphanilamide in phanilamide group and controls: stippled columns, sensitive growth at 2 mg. per 100 ml.); hatched columns, partially istant (growth at 2 mg. per 100 ml.); black columns, resistant owth at 10 mg. per 100 ml.). Number of strains tested: group A ; group C, 107; group G, 161.

one of our patients experienced major toxic reactions ranulocytosis, severe anæmia, or exfoliative dermatitis) very few developed minor effects, such as morbilliform es and erythemas, during the entire period of study. ic reactions, therefore, have been conspicuously mportant. Though this finding is consistent with experiences of most American workers except well and Button (1941) and Kuttner and Reyersbach 43), we do not recommend chemoprophylaxis unless ients can be observed at regular intervals and appro- ite laboratory examinations can be made. In this ic routine clinical and laboratory examinations were de on the patients up to the age of 14, when they were nsferred to a hospital for adults.

he development of sulphanilamide-resistant strains of molytic streptococci has been demonstrated, and as been shown that this change is permanent in most the cultures. There was no evidence to suggest that s mutation was associated with any loss or gain in ulence of the organism. The question now arises ether the clinical benefit of prophylaxis is counter- anced by the potential danger associated with the development of sulphonamide-resistant organisms. In answering this question we must consider the issue from two points of view, that of the individual and that of the community in which he lives. From the individual point of view we have shown that chemoprophylaxis is of benefit in that it offers a significant degree of protection against recurrent streptococcal implantation. From the community angle benefit must also be derived since prophylaxis effectively reduces the carrier-rate which in turn must reduce infection pressure irrespective of whether we are dealing with a semi-closed community, such as a convalescent home, or an open urban community. The development of resistant strains, if there is no change in virulence or infectivity, cannot increase the infection-rate, since the incidence of infection is independent of this factor. Accordingly, resistant strains developing in a relatively small and selected group of the total population, such as rheumatic children, is not an epidemiological but a therapeutic problem, and, as already pointed out, penicillin provides a more than adequate substitute in case of manifest infection. Once the decision is made, treatment should be pursued continuously over the recurrence-susceptible years with adequate clinical, hæmatological, and, possibly, bacteriological supervision. The development of resistant forms, particularly in chronic carriers, is no indication for the cessation of prophylaxis, since the treatment still affords protection against reinfection with sensitive strains.

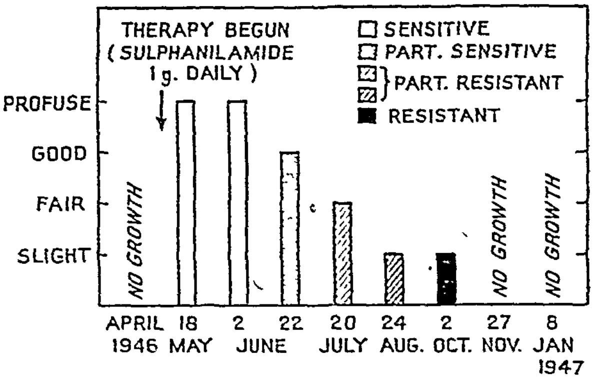


Fig. 10—Development of resistance to sulphanilamide during prophylaxis.

It may be asked which cases of rheumatic fever should be selected for treatment, when should therapy be instituted, when should this treatment cease, and what sulphonamide should be used? We consider that all patients who have had undoubted rheumatic fever or chorea should, if circumstances permit, be given the benefit of this treatment. It would be wrong to assume that it is indicated only for the moderate or severe cases, and that the mild cases in which the patients are discharged after three months' stay in hospital with no apparent cardiac damage can be ignored. A typical case from our series was in a child who had a mild attack of rheumatic fever at the age of 7 years and developed a polyarthritis with an associated carditis. This child was kept in hospital three months and discharged perfectly well. A year later he had a recurrence almost identical in nature and severity with his first attack. At the age of 12 years (five years later) he had a second recurrence and on this occasion showed pronounced mitral and aortic valvular changes, which have persisted. It was only after this second recurrence in 1944 that sulphanilamide therapy was begun; and, while he was under treatment he had no further recurrences. This initially mild case is typical of many in which repeated recurrences eventually lead to a state of gross valvular damage. Accordingly, chemoprophylaxis must be considered for all cases of rheumatic fever irrespective of the severity of the first attack.

antagonism is not completely successful, especially in children with enlarged tonsils, who tend to become chronic streptococcal carriers.

SULPHANILAMIDE RESISTANCE

The reluctance of clinicians to introduce continuous sulphonamide prophylaxis is partly due to the fear of developing sulphonamide-resistant organisms in the individual and in the community. This is understandable in view of the unfortunate experiences in the United States Naval Forces (Damrosch 1946, Delamater et al. 1946, Epidemiology Unit No. 22 1945, Roberg 1946, Wilson 1946) and the well-authenticated reports that drug-fastness tends to develop after prolonged and inadequate dosage (Colebrook et al. 1944, Hendry 1942). However, the arguments that called for caution in military establishments in 1945 are somewhat academic when applied to a restricted portion of civilian communities in 1949. In treating rheumatic children we are dealing with a very small fraction of the total or child population; hence the danger of dissemination of drug-resistant organisms is correspondingly small, and in the event of serious illness due to sulphonamide-fast organisms other chemotherapeutic agents, such as penicillin, are readily available. Though Baldwin (1947) did not encounter sulphadiazine-resistant streptococci in children given sulphadiazine prophylactically, our experience has been somewhat different. It will be seen from the results of tests on 669 strains of hæmolytic streptococci by Harper and Cawston's (1945) method that there was an increase in the number of resistant forms isolated from the treated group (fig. 9). For example, in a comparison of organisms from control and sulphanilamide groups the increase in resistant strains was from 6 to 29% in group A, from nil to 13% in group C, and from 28 to 66% in group G.

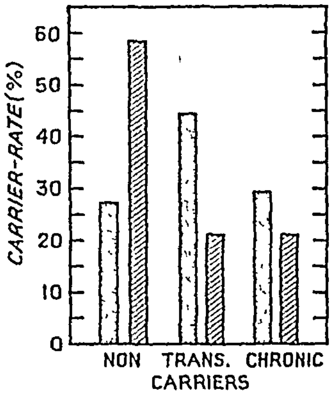

Fig. 8—Group-A hæmolytic streptococcal carrier-rate in sulphanilamide group (hatched columns) and in controls (stippled columns).

These findings call for comment in an attempt to reconcile them with the clinical benefits already described. The first point to be emphasised is that, *quantitatively*, prophylaxis lowers the streptococcal carrier-rate and hence lessens the risk of manifest infection and its sequelæ. Secondly, the development of sulphonamide-resistance is a gradual process during which the degree of infection appreciably wanes owing to natural defence mechanisms. This was well shown in a patient who contracted a group-A type Woodbury infection shortly after the start of sulphanilamide prophylaxis. The fate of this organism and its changing resistance are shown in fig. 10.

Another aspect of the problem of drug-resistance which received our attention was the permanency of this change. Twelve resistant strains were subcultured daily in sulphonamide-free serum-broth for five weeks. The sensitivities of the original and passaged cultures under identical conditions are shown in table V. It will be noted that most of them retained their original resistance after as many as 25 subcultures in the absence of sulphanilamide, and for this reason the change must be regarded as permanent. These findings provide little support for discontinuing prophylaxis in the hope that there will be a reversion of sensitivity during temporary cessation of treatment. This contention is

TABLE IV—INFLUENCE OF PROPHYLACTIC SUL *ON CARRIER-RATE OF GROUP-A HÆMOLYTIC*

Patients' group	No. of children	No. of swabs	Average no. child	Average interval	Non-	Tr
Control ..	63	608	10	2·5	27%	44

Chronic carrier, 4 or more positive swabs.

further supported by our observation of thre who continued to harbour sulphanilamid organisms for several weeks after withdrawal of amide. Hence the indication for maintainin in the presence of resistant organisms is the offered against exogenous reinfection by sulp sensitive strains.

DISCUSSION

The object of the present study has been the value of prophylactic sulphanilamide th *method of reducing recurrence-rate in rheum* We intentionally refrained from expressing an this question until sufficient data had been *to satisfy the most rigorous requirements of* analysis. Thus the present work covers about a half years' observation of 548 patients, a tot person-years. During this time 134 recurrences which were in a form severe enough to warrant to hospital and which fulfilled the diagnostic Jones (1944). The patients were divided into tw one receiving prophylactic sulphanilamide and serving as a control. The two groups were closely particular attention being paid to (1) age-dist (2) time of start of prophylaxis in relati major episode; (3) severity of initial attack; susceptibility towards recurrence due to factors.

The results of this study showed the recurrence-rate for children aged 4–14 years to and that prophylaxis reduced this figure to 3·2 *figures are statistically significant.*

On the basis of these results and those of ot there is little doubt that continuous prophylactic amide administered in doses of 1 g. daily to patients who have had one or more attacks of fever will significantly reduce the risk of recurrence.

Simultaneously throat swabs were taken from *visiting the clinic during the same period.*

al tumours of the kidney form a single group. ted subdivision of this group of common renal s arises either from antiquated views on histogenesis ignorance of the wide range of structure to be seen group and even in one tumour. 'Grawitz tumour,' nephroma,' 'clear-celled carcinoma,' 'solid-celled ma,' &c., are not separate kinds of tumours but names which have been given to the single entity, ma of the renal parenchyma."

his view of renal tumours is accepted by most ists is, I think, true, but the reorientation of to accord with this view of the unity of kidney is (other than the embryonic nephroblastomas) nterpret the findings of carcinoma cases with hological findings as are cited below is slow to e.

llowing statements on ætiology and pathology n from Willis's book.

nce.—In Willis's own series of 1060 necropsy ich were all studied microscopically the incidence oma of the kidney was $2^1/_2$% (27 cases). This it a tenth of the incidence of gastric, and a third of pulmonary, neoplasms.

About half the cases occurred in the fifth and cades, the highest proportion being in the sixth It was rare under the age of 30. Willis's t patients were aged 29, 30. and 32. The mean eath was 58.

There was a preponderance of males over ; the ratios in published reports range between l 5 : 1 males to females.

of Tumour.—Young tumours are invariably in the cortex of the kidney.

l Factors.—There is a clear relationship between na and adenoma of the kidney, and there is for the almost invariable origin of adenomata rplastic foci in damaged kidneys. However, y only some carcinomata arise from pre-existing ata. for in only a few cases do carcinomatous show evidence of nephritis or of arteriosclerosis usually accompanies adenomata.

Structure and Growth.—The seeming circumscrip- l expansive lobular appearance of the tumours; ariable bulk, from small adenoma-like tumours masses weighing many pounds; their yellow ge colour, rendered all the more variegated by of fibrosis, necrosis, hæmorrhage, and cystic ; and their grossly polypoid invasion of the elvis and main veins are all familiar features.

scopic Structure.—The cellular make-up is very : (1) "clear-celled" type of growth is very ive; (2) solid-celled papillary adenocarcinoma is n: (3) anaplastic variants, spindle-celled or rphic-celled, and often diffuse and sarcoma-like earance, have led to many erroneous diagnoses "sarcoma" or "mixed" tumour (case 4); and ly vascular and hæmorrhagic tumours also used a source of confusion in histological diagnosis ithelioma," "endothelioma," "angiosarcoma").

stases.—These are very fickle and unpredictable r behaviour. Some grow for long periods and to izes without yielding metastases (case 2), whereas remain small and symptomless yet produce large metastases usually by the blood-stream (case 3). atic growths have caused many errors of diagnosis. nephrectomy metastatic growths may soon appear lungs, bones, or elsewhere, or they may not appear ix, eight, or ten years later. Perhaps more often ny other tumour renal carcinoma produces solitary rs in bone, brain, or other tissues; and it has claimed (Smyth 1939) that surgical removal of primary and secondary growths is sometimes ve in such cases, a claim which, it need scarcely be said, should not be made until there has been long postoperative freedom from recurrences.

In about 50% of Willis's necropsy cases the lumbar glands were involved, and in about the same proportion involvement occurred in glands regional to organs containing metastases. Blood-borne metastases were found in the lungs in three-quarters, in the liver in half, and in the skeleton in nearly half of fatal cases. Such metastases in the skeleton often simulate primary disease of bone. Metastases in the brain (see cases 3 and 4) occur in a quarter of fatal cases; hence carcinoma of the kidney is the third commonest tumour to give rise to metastases in the brain (after neoplasms of the lung and breast).

CLINICAL PICTURE

The classical clinical triad of hæmaturia, pain. and tumour is now recognised to be found only late in the disease if at all. Hæmaturia, generally painless, is usually given as the most frequent first symptom and one which requires full urological investigation in patients of carcinoma age.

Of the cases presenting with secondaries, the lungs, the liver, the skeleton, and the brain are the common sites in order of frequency. Secondaries in the lungs often show a suggestive cannon-ball radiological appearance but may mimic primary lung carcinoma (case 3). A review from the files of 6577 necropsies by Hale and Burkland (1943) revealed 54 carcinomata of the kidney presenting silently with the result that no evidence for the true diagnosis was found during life.

PROGNOSIS

Judd and Hand (1929), in a review of 367 cases of carcinoma of the kidney seen at the Mayo Clinic between 1901 and 1928, found that 106 (51·5%) of the patients who had undergone nephrectomy were alive 3–20 years after the operation, 36% had survived 5 years or more, and 13% had survived 10 years or more. They state that "some were known to have metastases at the time of operation, and from the evidence at hand it would seem that the condition was arrested for a time. Therefore even in these cases nephrectomy would seem to offer a reasonable degree of palliation." Abeshouse and Weinberg (1945), in a series of 34 cases of carcinoma of the kidney, found the five-year cure-rate to be 35% and the ten-year cure-rate 20%.

CASE-RECORDS

Case 1.—A man, aged 42, was seen on Oct. 24, 1944, complaining of recent faintness and giddiness, attributed by him to migraine though without headaches. Melæna had been observed, without diarrhœa. His friends had noted his pallor.

Family History.—The patient's mother and his maternal grandmother had been obese and subject to migraine. His mother had died of carcinoma of the transverse colon. His father had died of uræmia after urinary calculus.

Previous History.—The patient had been subject to migraine from the age of ten years. The migraine had originally been severe, with vomiting, but now usually consisted of left frontoparietal headache lasting for one or two days, with nausea, and relieved by injections of ergotamine tartrate. The patient had had psoriasis. In May, 1943, when he had been examined for migraine, he had had abdominal obesity, a blood-pressure of 180/110, and a trace of albuminuria, with slightly impaired water-elimination test.

On examination the patient was pale and had a systolic blood-pressure of 130 mm. Hg. No other physical signs beyond abdominal obesity were found.

Blood-count.—Red cells 3,160,000 per c.mm., Hb 5·35 g. per 100 ml., colour-index 0·57, white cells 10,000 per c.mm. (polymorphs 70%).

Stools were positive for occult blood.

Barium Meal.—Findings suggested chronic gastritis with no evidence of ulcer or neoplasm. An oval opacity with clear centre near the duodenal loop suggested a gall-stone.

Prophylaxis should be instituted when a quiescent state has been reached after a major episode, preferably the first attack. This would probably be about three or four months after the onset of the episode, when the patient is about to be discharged from the convalescent hospital. The start of prophylactic therapy at this stage will have none of the untoward reactions which may arise if treatment starts in the acute phase (Massell and Jones 1938, Swift et al. 1938).

As to when sulphonamide prophylaxis should be stopped we have little factual information. Baldwin (1947) found no evidence of increased susceptibility towards recurrence on withdrawal of sulphadiazine.

Our experience, with few exceptions, has been restricted to the observation of children up to the age of 14, when they are discharged from the clinic and prophylaxis becomes the responsibility of the hospital for adults. It is evident that the tendency towards recurrence decreases as age advances, but in unusual circumstances, such as entry into an environment of high infection pressure—e.g., a military establishment—rheumatic fever can and does recur in adults. Hence the decision to discontinue prophylaxis after treatment during the recurrence-susceptible period must be determined for each patient according to his cardiac status and his environment.

As to the choice of sulphonamide, we have had little experience. The work reported here was begun in 1944, when the newer sulphonamides were unobtainable, and we have persisted with the same drug, sulphanilamide, to accumulate sufficient data on its effectiveness. More recently we have been using sulphadiazine in average daily doses of 0·5 g., but it is too soon to make any comparisons. In view of the close parallelism between our findings and those of American reports for sulphadiazine prophylaxis there appears to be little to choose between the two drugs.

SUMMARY

The influence of prophylactic sulphanilamide therapy in children with rheumatic fever is assessed on a clinical and bacteriological basis.

The recurrence-rate in 211 children aged 4–14 years who were maintained on small daily doses of sulphanilamide for 565 person-years was 3·2%. In a control group of 337 children, closely matched with the treated group and studied simultaneously for 971 person-years, the recurrence-rate was 11·8%.

The hæmolytic streptococcal carrier-rate in the two groups of patients was determined by repeated throat cultures, and a significant reduction of group A was observed in the treated group.

Sulphanilamide-resistance tests on 669 strains isolated from both groups of patients revealed that 29% group-A strains isolated from the treated group and 6% from the controls were resistant to 10 mg. of sulphanilamide per 100 ml.

The following conclusions have been reached:

Sulphanilamide prophylaxis is of definite value in reducing the recurrence-rate in rheumatic fever.

Treatment should be available to all patients provided adequate clinical and laboratory control is exercised.

Treatment should begin in the quiescent period following a major episode and should be continued at least during the recurrence-susceptible years—i.e., up to the age of 14 years.

Toxic reactions to sulphanilamide are minimal and seldom a contra-indication to prophylaxis.

The development of sulphanilamide-resistant organisms in these patients is not an indication to discontinue therapy.

We wish to thank the staff of the records office, Miss M. Tricks, and the medical registrars attached to the clinic for their assistance; and Miss L. Nutting for drawing the charts.

CARCINOMA OF THE KIDNEY

E. D. H. COWEN
M.D. Camb., M.R.C.P.
ELMORE RESEARCH STUDENT OF THE UNIVERSIT
OF CAMBRIDGE

IT has long been appreciated that carcinoma (kidney can be responsible for very varied clinical dromes, but as a rule there are pointers in either sy or clinical signs to suggest a renal origin for the p. tumour.

I report here 4 difficult cases, with widely di symptoms, seen in the last four years, which w shown at necropsy to be due to renal carcinoma none of the 4 cases was the correct diagnosi clinically, despite biopsy specimens in 3 cases. In case only were there symptoms or signs referable t urinary tract.

The cases are reported because it is felt that c medicine lags behind pathology in this disease ar re-emphasise the frequency of clinical and pathol misdiagnoses. This may be of more than acad interest, since a renal tumour can produce l syndromes at a time when it may well be remo by surgery (case 2) and the five-year survival following nephrectomy is probably about 35% (and Hand 1929, Abeshouse and Weinberg 1945).

In each of these cases the diagnosis of carcino the kidney came as a great surprise to all the clini concerned, and, though extensive investigations made in each case, in only one was pyelography formed. Therefore it seems worth while to per pyelography in all cases of suspected neoplastic di when no primary growth can be found.

ÆTIOLOGY AND PATHOLOGY

In computing data on renal carcinoma Willis (has emphasised the importance of using only t necropsy cases in which the diagnosis has been con by microscopy. He opens his remarks on carcino the kidney with the following sentences:

> "Excluding the tumours of the renal pelvis an embryonic nephroblastomas, all of the remaining mal

peration specimen (case 2) of renal tumour, showing charac- appearance of carcinoma of kidney. Note extreme similarity figs. 2 and 3, suggesting that "liver biopsy" was actually of large carcinoma of right kidney, since there were no ries in liver at this date.

of a gastric ulcer, and evacuation of the patient q was arranged. In April he arrived at No. 1 British Hospital, Karachi, where he was treated with diet lis with little benefit. He was placed in category hree months. His symptoms continued without a, though he gained about 1 stone in weight, making t 13 stone. In September he was further investigated me hospital. Barium-meal examinations on two occa- wed no gastric lesion. Tests for occult blood in ls were negative. "Neurotic dyspepsia" was diag- nd the patient was invalided to South Africa. In , 1943, he reached Oribi, Natal. Pain was still us, though he felt better. A barium meal showed abnormal. The patient was placed in category C ic dyspepsia. In April he arrived in Mombasa and ted to H.Q. East Africa Command. He continued spite of persistent pain. In May he was admitted 2 General Hospital, Nairobi, where enlargement of r was noted and *entamœba histolytica* was found in ls. He was not jaundiced. He was treated with ctions of emetine gr. 1. Aspirations of the liver tempted without success. The patient complained thlessness on exertion at this time. He was given tional six injections of emetine gr. 1. In August he nsferred to the 83rd General Hospital, where his as found to be palpable four finger-breadths below t costal margin. Radiography of the chest showed phragm to move evenly on the two sides. Liver- n tests were normal. An unsuccessful attempt was t liver-puncture biopsy. The patient was placed in y E by a medical board as a case of cirrhosis of the d embarked for the United Kingdom.

patient reached England in November, 1943, and was January, 1944, to the British Postgraduate School don for further investigation of unexplained hepato- . He was then a slightly apprehensive thin man g 10 stone 10 lb. in his clothes, with no abnormal l signs in any system beyond his liver, which could ated four finger-breadths below the right costal margin. rine was normal. A blood-count showed 5,300,000 lls per c.mm., Hb 95% (Sahli), white cells 9000 per with normal differential count. His erythrocyte- ntation rate was 1 mm. after 1 hour (Westergren). Kahn, plasma-bilirubin, blood-phosphatase, fasting sugar (90 mg. per 100 ml.) estimations were all normal. graphy of chest and abdomen showed lung fields normal, domes of the diaphragm moving freely, and no cencies of the liver shadow. Radiography of skull, and long bones showed nothing abnormal except a rarified area of the right parietal bone—? irregular ar groove. Eight stool examinations were negative for and ova, except two which showed cysts of *endolimax* fat analysis was normal; and three stools were ve for occult blood. Bromsulphthalein and intravenous ose liver-tests were normal. A liver-biopsy specimen efinitely abnormal, but, unlike any of the commoner lesions, chronic inflammatory lesion (Prof. H. Dible). atient was referred by Lieut.-Colonel W. R. M. Drew ank) to Westminster Hospital.

admission to Westminster Hospital in October, 1944, symptoms already described above the patient was r thin, alert, and slightly nervous. The only abnormal cal sign found was enlargement of the liver to four finger-breadths below the right costal margin. The right kidney could just be palpated. Laparotomy was agreed on as being the most likely way of elucidating the nature of the hepatomegaly.

Laparotomy (Mr. G. T. Mullally, Nov. 1).—A carcinoma of the right kidney was found as big as a football and well encapsulated, with no involvement of the renal veins. No evidence of metastases was seen. The liver was normal in size, shape, and consistence but had been displaced downwards by the renal mass. The tumour was removed with much loss of blood and with shock, which was treated with serum and blood-transfusions.

Progress.—Postoperatively the patient developed a thrombosis of the right internal saphenous vein from the ankle to the knee. On discharge from hospital on Nov. 27 he had a serum-alkaline-phosphatase level of 6 units; and radiography of the chest, long bones, spine, and skull was normal except for the (?) enlarged vascular channel of the right parietal bone. Comparison of a section from the operation specimen of the tumour with the "liver-biopsy" specimen showed identical histology (figs. 2 and 3), suggesting "liver-biopsy" was in fact tumour biopsy, the tumour having displaced the liver and occupied its site.

In June, 1945, the patient had developed skin recurrences near the operation wound and of both iliac fossæ, and radiography showed a shadow in the right superior mediastinum. The patient was given deep X-ray therapy. On July 23 he died in hospital with signs of right pleural effusion and gross hæmorrhagic ascites.

Necropsy.—Secondary deposits were seen in the liver, peritoneum, right kidney bed, iliac fossæ, right pleural cavity, and mediastinal glands. The left kidney was normal macroscopically. There was no evidence of growth in the renal veins or vena cava. The stomach appeared healthy.

Case 3.—A married woman, aged 65, had had a sudden onset of mistiness of vision of the right eye, with no diplopia and no pain, in October, 1946. She had been seen by an ophthalmic surgeon, who had found no abnormality. A week later her right upper eyelid had drooped, and soon afterwards the patient had been unable to open her eye. This had been accompanied by pain behind the right eye and on the right side of forehead and head to the vertex, and to a lesser extent behind the right ear. This pain had been associated with numbness. It had come and gone without apparent cause, but it had particularly been brought on by sneezing or by any sudden event, such as the banging of a door.

Family History.—The patient's father had died of old age at the age of 81, and her mother of cancer at the age of 89. There was no familial disease.

Past History.—The patient had had attacks of diarrhœa lasting from ten days to three weeks every month or so for twenty years, and she had passed fæces and mucus in the attacks. Sometimes she had not been able to control defæcation. Varicose veins with ulceration of legs had been present for thirty years.

On Examination (Nov. 22, 1946).—The patient was an alert woman of healthy appearance who was an active housewife. Abnormal physical signs were confined to cranial nerves: (1) smell was said to have been defective from birth; (2) the patient wore glasses at all times, though crude clinical tests did not show any apparent defect of vision; (3) there was complete paralysis of all the extrinsic muscles of the right eye, with complete ptosis and an immobile but not dilated pupil on the right side; and (4) there was partial loss of sensation over right ophthalmic fifth nerve. The size and sounds of the heart were normal. Blood-pressure was 180/85.

Investigations.—Serum Wassermann and Kahn reactions were negative. Radiography of the skull did not reveal any abnormality. On lumbar puncture the cerebrospinal fluid was clear, with normal cytology and chemistry and under a pressure of 85 mm. H_2O, and gave a negative Wassermann reaction. Blood-counts showed normal numbers of red and white cells.

The patient was discharged from hospital with the provisional diagnosis of atheromatous aneurysm of the right internal carotid artery.

Readmission.—Six weeks later the patient was readmitted. Ten days before, in outpatients, the left eyelid was seen to be closing. This had progressed since and was accompanied by pain over the left eye. Five days before readmission the patient had had a sudden hæmoptysis of about $^3/_4$ pint.

The remainder of the gastro-intestinal tract was normal. A further barium meal by Dr. Cochrane Shanks revealed that the "opaque gall-stone" was really a projection into the duodenum encrusted with some opaque material. A polyp of the duodenum was tentatively diagnosed.

Laparotomy (Dec. 16, 1944).—Mr. N. C. Lake reported: "The patient was very fat and the whole operation was rather difficult on this account. I felt a mass the size of a large chestnut projecting into the lumen of the descending duodenum. The mass was on the back wall and apparently very adherent to an enlarged right kidney. At one moment I thought it arose from the kidney but decided that the mass arose in the duodenum and had become adherent to the kidney pelvis. In the mass of fat I could not feel the left kidney (this was subsequently proved by pyelography in April, 1945, to be present). I opened the duodenum and examined the highly vascular mass which obviously invaded its posterior wall. I removed the more superficial portion of the tumour, but the deep portion was so fixed posteriorly (for reasons which ultimately became clear at necropsy) that I decided against an attempt at radical removal. I closed the duodenum, did a gastro-enterostomy, and removed some stones from the gall-bladder (these were non-opaque and had not shown on radiology of the abdomen."

The biopsy specimens were seen independently by three pathologists, Dr. F. Kellett, Dr. H. W. C. Vines, and Dr. M. Haines, who all concluded that a hæmangio-endothelioma was present (fig. 1).

Radiotherapy.—The patient was admitted to Westminster Hospital in January, 1945, for radiotherapy to duodenal tumour (Dr. F. Allchin). A total tumour dose of about 1870 r (Westinghouse) was given between Jan. 24 and April 18. During this time the patient had recurrent slight bleeding from the gastro-intestinal tract and a large hæmatemesis (2 pints) for which 2 pints of blood was transfused.

Further Investigation.—In March, 1945, a mass was palpable deep in the right hypochondrium close to the midline, fixed, firm, and non-tender. Further investigation of the renal tract was undertaken with particular reference to the functioning of the left kidney. In April an intravenous pyelogram showed a very large hydronephrosis of the right kidney with no localised deformity of the renal pelvis. The left side showed normal filling, with a slightly full renal pelvis. The dye excretion-rate was very slow. A urea-clearance test in May, 1945, showed 74% of average normal renal function. Blood-urea was 26 mg. per 100 ml. A trace of albumin was present in the urine, but no red blood-cells or abnormal cells were seen.

Progress.—The patient was weak and anæmic but was now afebrile, with blood-pressure 110/65, and was discharged home convalescent on May 7, 1945. He remained well though weak till readmitted on Oct. 16 with severe recurrent hæmatemeses, necessitating 8 pints of blood by transfusion during the first week. During this week he was severely ill with sustained fever and had two rigors (no evidence of incompatible blood-transfusion was present). Suddenly his

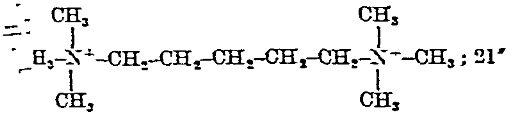
UNIVERSITY COLLEGE HOSPITAL, LONDON

eir investigation of the pharmacological properties homologous series of polymethylene bistrimethyl-ium compounds Paton and Zaimis (1948a and b, found that both the pentamethylene and hexa-ene members paralysed transmission through the mic ganglia.

amethylene bistrimethylammonium di-iodide (now as pentamethonium iodide) has the following a:

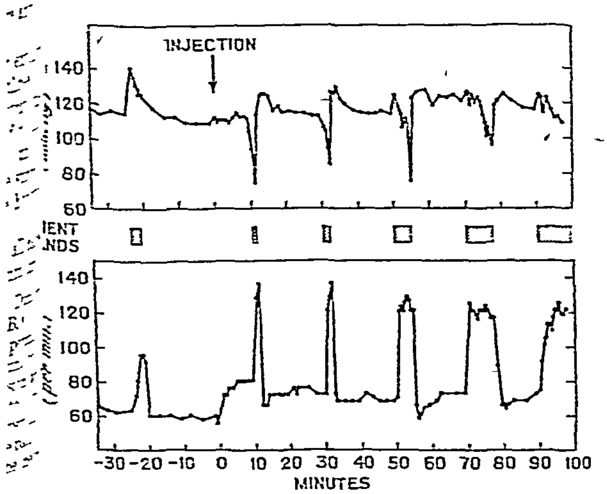


$$H_3-\overset{CH_3}{\underset{CH_3}{N^+}}-CH_2-CH_2-CH_2-CH_2-CH_2-\overset{CH_3}{\underset{CH_3}{N^+}}-CH_3 ; 2I^-$$

white powder, freely soluble in water. The solution le and is sterilisable by autoclaving.

on and Zaimis showed that, in cats, intravenous on of pentamethonium iodide caused relaxation nictitating membrane, excited to contraction by glionic stimulation, but did not alter the effect tganglionic stimulation. It also caused a fall of pressure in cats anæsthetised with chloralose, ect which was inhibited by the previous administra-f nicotine. Pentamethonium iodide prevented the cardia normally produced by stimulation of the eral end of the cut vagus. From these and other s Paton and Zaimis concluded that, in animals, incipal site of the drug's action was at the ganglionic se. Pentamethonium iodide does not stimulate utonomic ganglia and is almost devoid of the sing properties of the higher members of the . In fact, it antagonises the curare-like action of ethonium iodide (Paton and Zaimis 1949, Organe 1949).

a preliminary trial of its action in man, Organe (1949) found that intravenous doses of 20–40 mg. well tolerated. Vasodilatation occurred after the injection; the blood-pressure, in the supine subject, did not fall, but postural hypotension was observed as late as 30 minutes after injection.



—Systolic blood-pressure and pulse-rate in a normal person before after the intravenous injection of 50 mg. of pentamethonium ide, showing the effect of posture. After the injection, the subject od up at intervals, for periods shown in black, until he felt faint had to lie down.

We have been investigating, at the request of the Medical Research Council, the clinical effects and possible uses of pentamethonium iodide. Its action has been studied in normal people, in patients with hypertension, and in patients with peripheral vascular disease. Its effect on the peripheral circulation is the subject of a separate paper (Arnold et al. 1949).

Pentamethonium iodide was used in a solution containing 50 mg. to the millilitre, and was given intravenously in doses ranging from 25 to 100 mg. It was injected within a period of 30 seconds, and the subject remained supine while under observation, except when tested for postural hypotension. It has also been given intramuscularly in doses up to 100 mg.

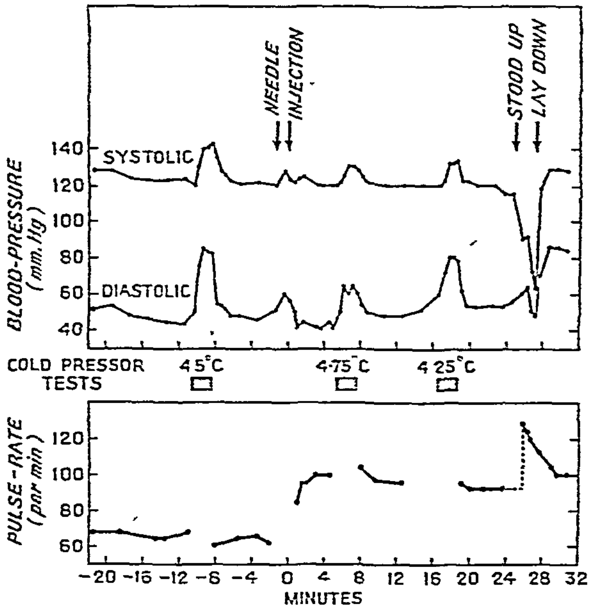


Fig. 2—Blood-pressure and pulse-rate in a normal person before and after the intravenous injection of 60 mg. of pentamethonium iodide, showing the response to immersion of the hand in cold water and to change of posture.

NORMAL PERSONS

In normal persons in the recumbent position intravenous injection of pentamethonium iodide produces no immediate subjective sensation. A transient feeling of warmth or fullness in the head, hands, or feet is occasionally noted within a few minutes of the injection; this is never well marked, and the tingling and coldness felt after injection of tetraethylammonium salts have been notably absent. Accommodation may be slightly impaired but not so much or so constantly as with tetraethylammonium chloride.

Objectively, suffusion of the conjunctivæ is often seen, and slight cyanosis of the lips has been observed on two occasions. Within a minute of the injection the pulse-rate usually increases by some 20–30 beats a minute. Little, if any, change in the blood-pressure occurs unless the erect posture is assumed, when well-marked hypotension results. Postural hypotension can be observed up to 1½ hours after injection (fig. 1). Vasodilatation, as measured by digital and pulse volumes, begins within 2 minutes and is still present 60 minutes after injection. Digital blood-flow and skin temperature also increase (Arnold et al. 1949). Doses up to 70 mg. modify but do not abolish the cold pressor response (fig. 2). The lack of change in blood-pressure after

She had been blind in her right eye for the past fortnight. She had become progressively weaker and more breathless and had lost weight (unknown amount). She had lost her appetite and had been too weak to walk.

On Jan. 8, 1947, there was a tremendous change in the patient. She was now slow, lethargic, and expressionless, and looked thin and very ill. There was complete bilateral external and internal ophthalmoplegia with fixed inactive pupils. There was no appreciation of light by the right eye. No optic atrophy was seen. The vision of the left eye was probably not impaired. Hypersensitivity of left ophthalmic fifth nerve was noted, with slight impairment of sensation of the right ophthalmic fifth nerve to cotton-wool and pinprick. Radiography showed no abnormality in the skull and a poorly defined opacity of the hilum of the left lung, extending towards the periphery. The right eighth rib was partially destroyed in the posterior axillary line, where there was an associated mass of soft tissue. A small diaphragmatic hernia was present on the left side. A carcinoma of bronchus with skull and rib secondaries was diagnosed.

Progress.—The patient's lower jaw muscles became so weak that she could not keep her mouth shut, and she died in coma on Jan. 24.

Necropsy.—The skull contained a soft mass of growth (4 × 3·5 × 3 cm.) apparently centred in the sphenoidal air sinus, whose walls had completely disappeared. The growth had extended rather more towards the right side than the left and had completely surrounded the right 2nd, 3rd, 4th, and 6th nerves. On the left side the 2nd nerve was constricted but not surrounded by growth. The 5th nerve on each side was situated near the margin of the growth, its anterior division, especially the right, being well within the growth. The pituitary was unrecognisable on the soft opaque brownish-red cut surface of the mass, though its stalk was well preserved. The growth had also invaded the dura to appear as a cluster of close-set rounded purplish-red nodules in the medial part of the right middle fossa.

Secondary growth in much enlarged bronchial lymph-nodes at the hilum of the left lung had compressed the left vagus nerve and its recurrent laryngeal branch below the aortic arch and deflected the left phrenic nerve. Microscopy showed carcinoma in the lymphatics around bronchi, near the hilum, and with a recent thrombus in a large pulmonary vein. An ovoid nodule of growth took the place of a length of the right eighth rib, bulging mostly inwards beneath the parietal pleura. The right kidney contained a rounded somewhat lobulated mass which appeared to have penetrated the renal capsule in one area and to have spread into the circumrenal connective tissue. The renal pelvis, renal vein, and inferior vena cava were not invaded. Macroscopically and microscopically this mass was a typical carcinoma of kidney. Some small veins were filled with growth.

Case 4.—A married woman, aged 62, was seen on Sept. 2, 1947, complaining of having had no energy and a poor appetite for the past three months.

Family History.—Her mother and her father had lived to over the age of 70. Her husband and daughter were well. There was no anæmia in the family.

Past History.—The patient had had no serious illness. Before this illness she had always been well and had plenty of energy. There was no evidence of loss of blood from any system. The patient had possibly lost a little weight. Her usual food was a normal mixed diet.

On examination there was definite anæmia, with no jaundice, glandular enlargement, or splenomegaly. The only abnormal sign in the central nervous system was loss of vibration sense in both ankles. The patient was running a continuous fever of 99–100°F with peaks to 103°F.

Investigations.—On Sept. 9, 1947, a blood-count showed red cells 2,000,000 per c.mm., Hb 5·2 g. per 100 ml., M.C.Hb 26 μμg., reticulocytes 5%, and white cells 13,400 per c.mm. (polymorphs 82%, neutrophil myelocytes 0·5%, Turk cells 1%). A histamine test showed a normal gastric secretion of hydrochloric acid. Occult blood was absent from three stools. Barium meal and enema revealed no abnormality. Serum-bilirubin 0·8 mg. per 100 ml. Serum Wassermann reactions negative. Blood-urea 33 mg. per 100 ml. Radiography of lung fields, thorax, dorsilumbar spine, pelvis, and femora showed no abnormality. The urine contained no albumin, cells, casts, or Bence-Jones proteoses.

A further blood-count on Sept. 23 showed a severe red cells 1,730,000 per c.mm., Hb 3·8 g. per 100 normal mean corpuscular volume but decreased content, giving a low mean corpuscular hæmog centration of 25·3% (normal 32–38%). This anæmia occurred despite massive iron and a therapy. Sternal marrow revealed normal cell an abnormal myelo-erythroid ratio of 1 : 1 and an of primitive cells.

Scrutiny of breasts, thyroid gland, and the surface on Sept. 26 revealed no evidence of neoplasm and vaginal examinations were also negative.

Progress.—On Sept. 27, the patient was given a of 4 pints of packed red cells. On Sept. 30, a showed red cells 2,450,000 per c.mm., and Hb 7·5 g. Two weeks later, despite the addition of liver ex folic acid to the iron therapy, Hb was 3·3 g. per and reticulocytes 0·2%. Repeated blood-counts steady fall in the total granulocytes, with an primitive cells and a slight but steady rise in the number of lymphocytes. On Oct. 4 a transfusion of of packed red cells were given. On Oct. 21 a bl showed red cells 1,990,000 per c.mm., Hb 5·85 g. per and white cells 7700 per c.mm. On Oct. 24 the pat in coma, having had generalised convulsions in three days.

Necropsy.—A carcinoma of the upper pole of kidney was found. There was no growth in the re The only affected glands were eight left para-aortic Growth took the place of 90% of the bone-marrow sternum, lumbar vertebræ, and femoar, with only islands of normal red bone-marrow. Both suprarenal were involved. There were a few small subcapsular in the liver. A subarachnoid hæmorrhage was p the lateral surface of the left cerebral hemisphere sylvian fissure; a few very small blood-vessels were bosed in the white matter of the cerebrum deep to and on the opposite side (right). Microscopy s carcinoma of the kidney of an unusual type, having abundant rather cellular stroma and relatively few or acini, with the result that many parts simulated nective-tissue tumour, but definite tubules were p were more obvious in some of the secondaries—e.g., suprarenal glands—than in the primary growth. spindle-shaped cells were present; these were elongated epithelial cells.

SUMMARY

Of 4 cases of carcinoma of the kidney, one p as gastro-intestinal bleeding, one as unexplained megaly, one as a lesion of an internal carotid and one as leuco-erythroblastic anæmia.

In only one of them was there any clinical sug of renal abnormality.

All 4 were misdiagnosed after extensive inve and despite biopsy specimens in three.

This series is presented to illustrate the extrao difficulty there may be both for clinicians pathologists in the diagnosis of a not uncommon ne disease. This is important, since surgical treatm carcinoma of the kidney is more hopeful than t most neoplasms.

Pyelography should be done in all cases where stases are present but no primary tumour can be fo

My thanks are offered to Dr. H. Dunlop (case 1) G. T. Mullally (cases 1 and 2), Dr. L. B. Cole (cases 3 and Sir Lionel Whitby (case 4) for permission to their cases; Mr. N. Lake for his account of the lapa in case 1; Prof. H. Dible for permission to reprodu liver biopsy specimen in case 2; the pathological depa of Westminster Hospital for the necropsy findings in 1 and 2 and all the photographs; and the pathological d ment of Addenbrooke's Hospital for the necropsy fi in cases 3 and 4.

ACQUIRED RESISTANCE TO PROGUANIL IN PLASMODIUM FALCIPARUM

D. R. SEATON
M.B. Camb., M.R.C.P.

A. R. D. ADAMS
M.D. Lpool, F.R.C.P.

From the Clinical Department, Liverpool School of Tropical Medicine

AFTER it had been shown that *Plasmodium gallinaceum*, maintained by serial blood inoculation in chicks, could readily be made resistant to proguanil ('Paludrine') by repeatedly giving subeffective doses of this substance (Bishop and Birkett 1947, Williamson et al. 1947) it became desirable to find out whether proguanil-resistance could similarly be induced in the human malarial parasites. This was shown to be the case with *P. vivax* (Seaton and Lourie 1949) ; in this paper it is shown that the same is true of *P. falciparum*.

A strain of *P. falciparum* was isolated in November, 1947, from a patient who had contracted malaria in West Africa. This patient had been taking proguanil intermittently during his infection, but without apparently increasing the resistance of his parasites to the level of ordinary therapeutic doses, since after he had come under our care a single dose of 300 mg. was sufficient to clear his peripheral blood of demonstrable parasites within twenty-four hours. Blood was taken from this man and inoculated into a neurosyphilitic patient and the strain has since been maintained by intravenous blood inoculation in a series of such patients.

As a rule, proguanil treatment was started in the subinoculated cases as soon as parasites were found in thick blood-films, though in 2 cases (2c and 6) the drug was given for some days before the patients were inoculated. Our aim was to adjust the initial treatment so that the doses given were insufficient to abolish the fever and parasitæmia but sufficient to prevent the development of cerebral malaria. This treatment was usually followed by a ten-day course of daily doses of proguanil, based on the observation by Fairley (1946)

DEVELOPMENT OF RESISTANCE TO PROGUANIL

Cases		Weeks since start of investigation	Initial treatment			Ten-day course		Relapse (days from end of ten-day course	Proguanil (g.) before subinoculation (main-line cases)

† Given mepacrine or quinine.

injection, the occurrence of tachycardia, the presence of postural hypotension, and the modification of the cold pressor response are shown in figs. 1 and 2.

HYPERTENSIVE PATIENTS

Pentamethonium iodide was given to fifteen patients with various forms of hypertension in the medical wards and, by Mr. J. G. Dumoulin, to patients with toxæmia of pregnancy. In hypertensive patients a sharp fall of blood-pressure usually follows intravenous injection. This begins within a minute and reaches a maximum within 2–5 minutes. The fall lasts much longer than with tetraethylammonium chloride, and a steady base-line is usually obtained (fig. 3). In a few patients the fall has been observed to persist for several hours (fig. 4). Tachycardia of about the same degree as in normal people usually occurs, and postural hypotension can be demonstrated. The subjective sensations in these hypertensive patients are again far less than with an injection of tetraethylammonium chloride.

In the accompanying table the lowest pressures obtained in six hypertensive patients given various doses of pentamethonium iodide, tetraethylammonium chloride, and 'Seconal' (a rapidly acting barbiturate) are compared. Those patients in whom tetraethylammonium chloride and seconal produce a large fall in blood-pressure also experience a large fall with pentamethonium iodide. A small fall is usually obtained in those whose pressure only falls slightly with the other two drugs. Discrepancies, however, occur, and the effect obtained with pentamethonium iodide is occasionally surprisingly great (cf. case 2). The table also shows the effect of varying the dose of the drugs, and from these and other results it seems that a dose of pentamethonium iodide will produce a fall of blood-pressure similar to that obtained with about ten times the weight of tetraethylammonium chloride. In addition, this response lasts longer (figs. 3 and 4).

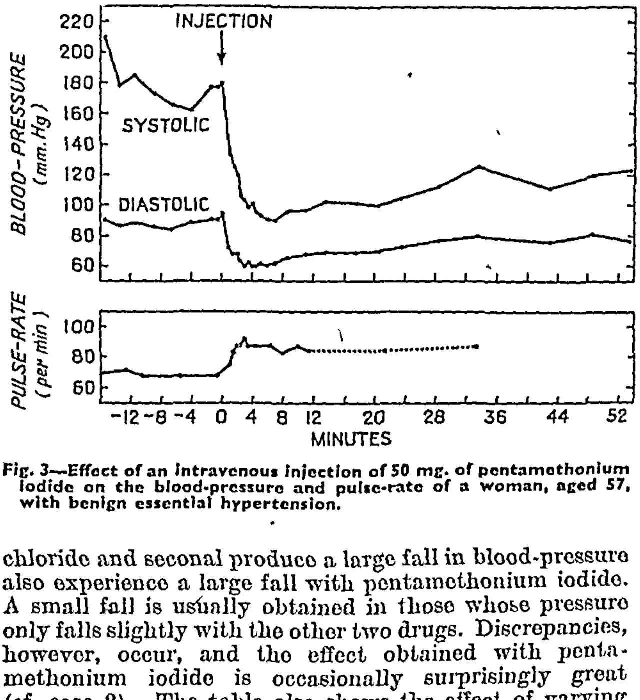

Fig. 3—Effect of an intravenous injection of 50 mg. of pentamethonium iodide on the blood-pressure and pulse-rate of a woman, aged 57, with benign essential hypertension.

Intramuscular injections of pentamethonium iodide have been used in only two cases and produced no local pain and no disturbance of bladder or bowel function. In a patient with chronic nephritis who had a sudden rise in blood-pressure, associated with headache, vomiting, and papillœdema, intramuscular doses, ranging from 20 to 75 mg., lowered the blood-pressure for periods up to 8 hours and relieved the headache. In one other hypertensive patient, with raised intracranial tension, an intravenous injection of 60 mg. produced an immediate fall in cerebrospinal-fluid pressure. Similar results have been reported with tetraethylammonium salts (Lyons et al. 1947), and this aspect of the action

pentamethonium iodide on the blood-pressure of a wo
with benign essential hypertension.

drugs is under investigation.

TOXIC EFFECTS

In one patient, with toxæmia of pregnancy, fall in blood-pressure was accompanied b This reaction is similar to that occasionally with tetraethylammonium chloride, but such may be more serious with pentamethoni Though the blood-pressure responded well to the lasting action of pentamethonium iodid further fall of pressure requiring repeated in adrenaline (fig. 5). The reaction in this patie a large initial dose (75 mg.), and it is now our start, in any patient, with a dose not exceedi In one other patient, however, an old man with and coronary vascular disease, an initial dose led to a fall in systolic pressure from 134 to 7 though the patient complained of no sympto blood-pressure rose spontaneously. In thre after repeated injections, a maculopapular rash developed. This cleared rapidly, ther *other symptoms suggesting iodism*, and on patients was subsequently given iodides with No other toxic effects have been observed.

DISCUSSION

The results so far obtained, in man, wi methonium iodide confirm that its action is that of the tetraethylammonium salts but potent and lasts longer. It is probably mor

l, and at St. Alfege's Hospital, Greenwich, and titoxin titrations at the Wellcome Research tories.

paper deals with items 1 and 2 only, but we have e that babies can be successfully immunised with recipitated toxoid (A.P.T.) starting at the age of s, provided that their passive antitoxin content len below 0·04 unit per ml. Work completed so ws that the presence of 0·1 unit of passive anti- er ml. interferes with active immunisation when t dose of prophylactic was 0·5 ml. of A.P.T. The of active immunisation will be published in ater.

TECHNIQUES

ction of Cord-blood Samples and Blood Samples abies.—In all cases the cord blood was collected he placental end, immediately after division of d and before delivery of the placenta. The anti- was estimated in the serum obtained from these s and from those taken from the mothers.

babies were bled by heel-prick, using a special designed by Mr. F. Tottem, which is detachable he $3 \times {}^3/_8$ inch tube on which it is used, and is sterilised by boiling. The tubes contained potassium e in solution, and the antitoxin was estimated plasma.

itoxin Titrations.—Estimations of antitoxin content made by the guineapig intracutaneous method. working out the distribution of antitoxic values considered sufficient to make titrations at approxi- twofold differences, and such values (see table I) corded as the highest value at which no reaction tained in the test (e.g., a value between 0·5 and 1 rded as 0·5). In the determination of the geometric of groups of figures, each antitoxic value was as the geometric mean of the two limits within it lay (e.g., a value between 0·5 and 1·0 unit is led as 0·707 unit). When accurate estimations required tests were made at 10% differences, and ntitoxic values were calculated by means of a la taking into account the nature of the readings ae intensity of the reactions produced in the guinea- y the different test mixtures. Owing to the small es of blood samples taken from babies, close testing ot possible except in those whose antitoxin content ufficiently high to permit of the testing of a dilution e serum.

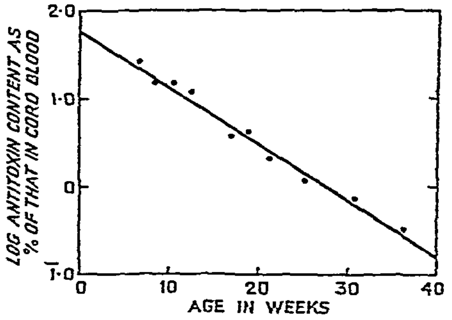
RESULTS

Distribution of Antitoxic Titres

Columns A and B in table I show the general distribution of antitoxic values in samples of cord blood taken at the two south-east London hospitals some 8 miles apart; no Schick tests had been made on these mothers, who represented a random sample of the population. Arranging these values into 7 groups (under 0·004 unit, 0·004 to 0·02, 0·04, 0·1, 0·2, 0·5, 1·0 unit and over) the difference in distribution between the two populations is not significant ($\chi^2 = 5{\cdot}719$; $P = 0{\cdot}46$).

Influence of the Schick Test on Antitoxic Titres

A group of expectant mothers at one of these hospitals was Schick-tested during the 4th month of pregnancy and the positive reactors were immunised with A.P.T. When the cord-blood samples were subsequently titrated for antitoxin, it was found that from 50 tested mothers who had been either Schick-negative (47) or positive-and-pseudo (3) no sample contained less than 0·04 unit per ml. and only one was below 0·1 unit; these women had not been immunised during pregnancy. From one other woman who had been recorded as Schick-negative the cord-blood value was less than 0·001 unit; she was excluded. The results of these 50 titrations are shown in column C of table I. Columns D and E give the values of the first 50 samples tested from populations A and B which contained 0·04 unit or more. The difference between the means of the logs of these values is not significant ($t = 1{\cdot}123$; $P = 0{\cdot}267$) but the difference between the means of the logs of groups C and D is highly significant ($t = 5{\cdot}19$; $P = 0{\cdot}001$). The values given in column C were obtained from women in the same district as those in columns A and D, and there seems to be a strong possibility that the difference between C and D was due to the Schick tests made on group C some months before delivery.



Rate of loss of passively acquired diphtheria antitoxin in babies.

Glenny and Allen[1] showed that the intracutaneous injection of a Schick dose of toxin into guineapigs and rabbits acted as a secondary stimulus and appeared to be as effective as the subcutaneous injection of 1·0 ml. of a toxoid-antitoxin mixture "suitable for human immunisation." In 1926 O'Brien[2] stated that several previously immunised children who had reverted to the Schick-positive state produced more antitoxin and became Schick-negative as a result of the test injection. An experiment has been started by one of us (M. B.) in collaboration with Dr. H. J. Parish with the object of measuring the antitoxic response of adults to a Schick test, and the rate of loss of the antitoxin so produced.

Rate of Loss of Passively Acquired Antitoxin

Fifty samples of cord blood were tested sufficiently closely to give a good indication of antitoxic value. Tests were also made on bleedings taken from the babies 6–38 weeks later. The rate of loss of antitoxin was calculated for each observation by dividing the age in weeks into the difference between the logs of the cord-blood value and that of the baby's blood at the time of

that 300 mg. of proguanil given daily for ten days was sufficient to cure infections with the New Guinea strains of *P. falciparum* with which he was working, so that in most cases the parasites were subjected to doses of two orders of magnitude. The strain was subinoculated in each case after varying amounts of proguanil had been given so that the parasites were exposed almost continuously to the action of the drug.

The progress of the experiment is shown in the table, from which it can be seen that by the tenth passage the strain was resistant to doses of 1 g. daily for ten days, which is at the upper limit of toleration of the drug. The question when resistance first appeared is more difficult to decide in the absence of any observations on the behaviour of the strain on its first encounter with proguanil, but from the second passage onwards the strain resisted doses of proguanil (100 mg. twice weekly) which we have found are ordinarily sufficient to control natural infections with West African strains of *P. falciparum* seen in Liverpool. But caution is necessary in drawing an analogy between the response to treatment of primary attacks of malignant tertian malaria and the relatively late cases which form a considerable proportion of the naturally infected cases treated by us, for the amount of treatment needed to clear the blood of parasites may be smaller in the later stages of the disease than in the initial attack, as was shown for quinine by James et al. (1932). The response of the strain to the ten-day course of proguanil was normal, in that parasites and fever disappeared before the fourth day, until the fifth passage when parasitæmia continued till the sixth day of treatment. From the seventh passage onwards the strain was unaffected by proguanil, in that parasitæmia persisted during all periods of treatment, though the intensity of the infection was probably to some extent diminished by the drug.

RETENTION OF RESISTANCE ON PASSAGE THROUGH MOSQUITOES

Attempts were made to infect batches of *Anopheles stephensi* on the patients of the eleventh and twelfth passages to determine whether the resistance would survive the sexual cycle of development in the mosquito. Considerable difficulty was experienced in doing this, for in the first two batches of mosquitoes fed the development of the parasites ceased in the oöcyst stage before sporozoite formation had occurred, although neither of these patients had been treated with proguanil. One mosquito of the third batch was found on dissection, sixteen days after the infecting meal, to have sporozoites in its salivary glands; these were inoculated intravenously into a patient, who developed overt malaria ten days later. After a further four days proguanil, 600 mg. daily, was given for three days and then 1000 mg. daily for six days. Parasitæmia continued throughout this ten-day course though on the last day the parasites were very scanty. Fever and heavy parasitæmia recurred four days after the proguanil was stopped, and a course of proguanil, 1000 mg. daily for twelve days, was then begun. The response was peculiar, in that fever and parasitæmia had disappeared by the fifth day but parasites were again detected on the eighth day and fever recurred on the tenth day. On the twelfth day, because of the patient's general condition, mepacrine was given. It is evident that the proguanil resistance was substantially unchanged by mosquito transmission of the strain.

DISCUSSION

The possibility arises of the production of proguanil-resistant strains in the field by inadequate treatment of malignant tertian malaria. At first sight it would seem more likely that this might occur than in benign tertian malaria since the resistance of our strain of *P. falciparum* developed more rapidly and to a higher degree than was
the case with *P. vivax* (Seaton and Lourie 1!
more, the margin between the minimal effe
the dosages ordinarily used in treatment
much smaller in *P. falciparum* than in *P*
tions; consequently the chance of unde
former disease is correspondingly greater.
hand, however, there is the extremely impo
tion (Fairley 1946, Mackerras and Ercol
et al. 1949) of the sterilising effect of
gametocytes, which in the strains of *P. fal*
examined prevented mosquito infection
during the administration of proguanil t
upon whom the mosquitoes are fed and f
afterwards. If these findings are genera
the prospects of the accidental develo
proguanil-resistant strain seem remote.

SUMMARY

A high degree of resistance to proguanil
in a strain of *P. falciparum* by giving sub
of the drug to a series of patients in wh
was maintained by blood-inoculation. T
was unaffected by mosquito transmission.

The accidental production in the field
resistant strains of *P. falciparum* is tho
because of the sterilising effect of the dru
cytes.

The clinical part of the work has been don
past 2½ years at Salomon's Welfare Ce

lowed them up for a longer time. The course se of undulant fever is unpredictable. Though rage duration can be calculated from an analysis numbers, there is no guarantee that a particular ill conform to this average. Spontaneous rapid y soon after admission to hospital is common and might easily be attributed to the treatment at the time. Relapse after apparent cure and ge from hospital is commoner still.

comparison of large series of cases treated by ove-mentioned methods with similar groups of ted controls has convinced me that the treatments itherto have had little or no influence on the of the infection. Also, some treatments seem to ate or prolong the disease, while others expose tient to unjustified risks.

discovery and introduction of the antibiotic ycin by Duggar (1948) has given rise to new Through the courtesy of Dr. Linton, of the e Laboratories Division of the American Cyanamid ny, I have been able to treat 24 cases of undulant with this new drug, and my results confirm those med by Spink et al. (1948) in Mexico. It is true the number of cases is relatively small and the d of observation so far too short to allow one to k with absolute certainty, but the results have been pressive that a preliminary report is justified.

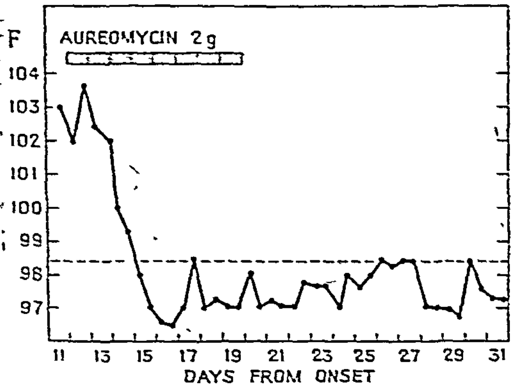

Fig. 1—Effect of aureomycin in case 1.

MATERIAL

series consisted of 12 males and 12 females, of from 11 to 55 years. Of these 24 cases, 7 were of severe or "malignant" type, and 2 patients were st moribund; 9 cases were of the undulatory type hich waves of pyrexia follow one another with or out intermission; 7 were of the continuous febrile , which runs a relatively low but continuous tem- ture for seemingly interminable periods; and the was a case of coxitis, afebrile at the time but with a itive blood-culture. The series was fairly representative he kind of case one encounters in Malta, with a ponderance, perhaps, of the severer types.

METHOD

he time at which treatment was started varied: atient was treated within fifteen days of the onset the infection, 6 patients within the first month, and within the first three months; while in the remaining ases the infection had been present for over six months. 2 of these the disease was over a year old and was l active.

In all but 4 cases the diagnosis was confirmed by ding the brucella in the blood before treatment. nfortunately in 2 cases the culture was contaminated d in the other 2 no growth was obtained.) But in all ese 4 cases the agglutination titre was so high that ere could be no reasonable doubt about the diagnosis.

Aureomycin has the great advantage that it is given by mouth, in capsules containing 250 mg. of the antibiotic. In the first 2 cases the drug was introduced gradually to avoid reactions, and it was not until the fourth day that the full dose of eight capsules (2 g.) was given. As no reactions were observed, and as some of the early cases were so severe that delay might have been fatal, the full dose was given from the start in all subsequent cases. The capsules were given one at a time every three hours. When an attempt was made to give them in twos, so as not to disturb the patients unduly, there were complaints of nausea, abdominal pain, and vomiting. In an attempt to economise the limited supply 2 children aged 11 years were given four instead of eight capsules a day, but the response was unsatisfactory and the dose had to be increased to 2 g. as in adults.

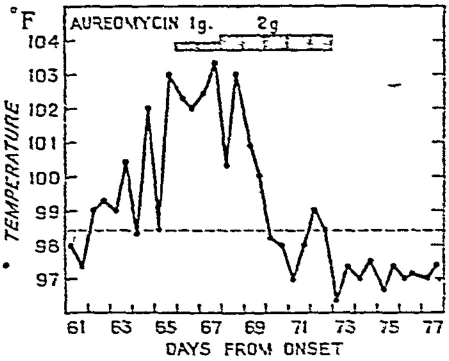

Fig. 2—Effect of aureomycin in case 2.

TOXICITY

There were no serious toxic reactions, though some of the patients were very ill before treatment was started and 2 had chronic nephritis. In some cases there was nausea, and, more rarely, vomiting and abdominal pain: 1 patient had diarrhœa for a day. But these symptoms were slight and insufficient to deter the patient from taking the capsules. Sudden and well-marked elevation of the temperature at the beginning of the treatment, graphically termed "spiking" by Spink et al. (1948), was observed in 3 cases where the temperature had been relatively low. There was a well-marked fall of blood-pressure in 2 of the severe cases, which gave rise to some anxiety at the time, but this might have been due to the severity of the infection. One patient developed urticaria on the tenth day of treatment, but the itching was easily controlled with 'Benadryl.'

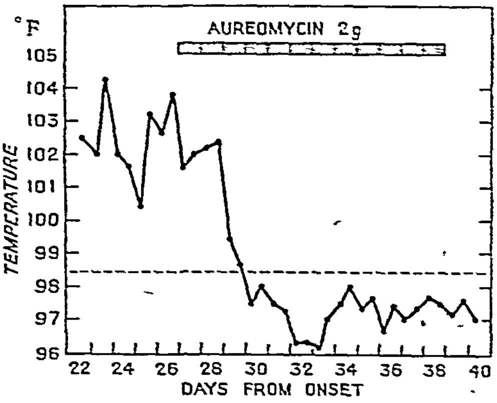

Fig. 3—Effect of aureomycin in case 3.

RESULTS

The immediate response was excellent in all cases. With one exception, in which the dose had to be increased to twelve capsules (2·5 g.), the temperature became subnormal within a maximum of four days after the establishment of the full dose of 2 g. As a rule there

TABLE II—DIPHTHERIA ANTITOXIN CONTENTS OF (A) ANTENATAL SAMPLES OF BLOOD, (B) CORD-BLOOD SAMPLES, (C) SUBSEQUENT BLOOD SAMPLES FROM MOTHERS, AND (D) BABIES' BLOOD

the observation. The results were grouped together according to the ages of the babies at the time when blood samples were taken, and the average weekly rate of loss determined for successive groups of five observations. The average amount of antitoxin present at the average age of each group was calculated in terms of the amount present in the cord blood. The results so obtained are plotted in the figure, and the best straight line calculated from the data is represented by the formula $\log A_w = \log A_c - 0{\cdot}20 - 0{\cdot}065\ W$, where A_w is the antitoxic value of the blood of a baby w weeks old and A_c is the cord-blood value. The formula shows that there is a steady logarithmic rate of loss of 13·9% per week falling from an initial average value 36·9% below that of the cord blood: the latter is thus 1·58 times the effective value of the babies' blood. On the average the antitoxin in a baby's blood falls to half about every $4^1/_2$ weeks, to a fifth every 11 weeks, and to a tenth every 15 weeks, starting from the initial titre 36·9% below the cord-blood value.

The amounts of diphtheria antitoxin found by titration in the serum of the 50 babies at various ages, arranged in groups of 5, are compared below with the values calculated from the formula given above.

30	5	0·64	0·74
36	1	0·28	0·31

Concentration of Antitoxin in the Cord Blood

In the early stages of the main experiment it was frequently noticed that the antitoxin content of the cord-blood sample was slightly higher than that of the mother's blood sample taken some weeks earlier, but there was no reason to expect the antitoxic titre to be still rising.

Direct experiments are now being made to compare the antitoxic titre of blood samples taken during labour (A), cord blood (B), and samples from the mother (C) and baby (D) a few days later; the results obtained so far are given in table II. It will be seen that in every instance except one the cord-blood value was considerably higher than that of the mother's serum although in almost all instances the mothers were bled for test less than 12 hours before delivery. The values given in table II all refer to mothers immunised during pregnancy in order to obtain titres sufficiently high to permit of close testing. Sufficient material was available in each case to ensure that the values were tested to an accuracy of well within 10% except those for mothers nos. 8 and 11. The antitoxin content of the babies' blood was in all five instances nearer to that of the mothers' blood
taken at the same time than to the content of
blood. In the two instances of mothers nos. 7
where the baby's antitoxin content was much
the mother's, the ratios of titres between cord
mothers' blood were the lowest recorded.
titre of the baby's serum (*no. 10*) was confirmed
on a further sample of blood taken 7 days la
tests are being made on the blood of babies.

SUMMARY

There was no significant difference in the
of diphtheria antitoxin contents of 100 sample
blood taken from each of two hospitals 8 miles
south-east London.

When expectant mothers were tested
immunised at the 4th month of pregnancy the
mean of the antitoxin content of the subsequ
blood samples from those either Schick-negativ
as positive-and-pseudo was over 0·5 unit per m
than that of the controls selected at random
same hospital.

The antitoxin content of cord blood was ver
ably higher than that of antenatal samples of the
blood taken during labour, and higher than
10 out of 11 samples taken after delivery; in 9 ou
11 cases the contents of the cord samples were
higher than the mother's after delivery.

There is a steady logarithmic rate of loss of
in babies which averages 13·9% per week, fal
an initial average value 36·9% below that of
blood. The average antitoxin content of the
babies 10 days old is half that of the cord blo
sequently the babies lose half their antito
$4^1/_2$ weeks.

Reviews of Books

hiogenic Carcinoma and Adenoma

M. FRIED, M.D., associate attending physician, ontefiore Hospital, New York. London: Baillière, ndall, and Cox. 1948. Pp. 306. 33*s.*

s well-produced and freely illustrated work is of ular interest at the present time, when an alarming se in the incidence of pulmonary cancer is being ised. Dr. Fried feels that the increase is more ent than real, and is due to such factors as ved diagnostic methods, public-health facilities, awareness."

sification of bronchial carcinoma is by no means but it can follow anatomical or microscopical ters, and conveniently enough these almost de. Assessment of ætiological factors, too. is lt: radon in cobalt mines (Schneeberg) and ium are now under suspicion, while the old rites—tobacco, tar products, silicosis, and viruses—nore or less exonerated for the moment. The al aspect and course occupy several chapters and ried describes fully hypertrophic osteo-arthropathy lation to pulmonary cancer. In a good account perior-sulcus tumours (Pancoast) he admits that most are bronchial carcinomas wedged in the some are derived from bronchial rests. The value of bronchoscopy and sputum-examination tressed and the dangers of aspiration biopsy

Fried notes that radiotherapy rarely gives results, and advocates radical surgery wherever ble. The chapter on bronchial adenomas indicates he regards these, on the whole, as benign urs arising from the basal cells of the bronchial ous membrane or from the mucous glands. A concluding section on mediastinal tumours includes iptions of dermoids, neurogenic tumours, and other entities.

e 118 illustrations are well produced, the photographs being particularly satisfactory. A number lustrative case-reports in each section help to cover cts not fully dealt with in the discussion. The le forms an authoritative work on a subject that is anding increasing attention.

métrites du col

(2nd ed.) P. DUREL, Hôpital Saint-Lazare. Paris: Masson. 1948. Pp. 334. 650 Fr.

this monograph Dr. Durel gives full descrip- us of the pathological anatomy, bacteriology, and tment of the infected cervix. Relatively little is l of symptoms. There is an excellent chapter on the interaction of the diseased cervix and pregnancy. The greater part of the book, however, deals with gonorrhœal infection, and for the gynæcologist who rarely sees overt gonorrhœa its value is correspondingly limited.

Under pathological anatomy the English reader will find much with which he is familiar; but Dr. Durel expands the standard pathological descriptions into an ingenious, though possibly over-elaborate, classification of types. The colposcope diagrams are well thought out, though somewhat crude in execution; indeed, many of the drawn illustrations would be better replaced by photographs and photomicrographs. The full chapters on bacteriology contain much detail on the morphology, staining, and cultural characteristics of the organisms concerned.

Therapeutic measures are discussed in great detail, and the chapters on the use of antibiotic and chemotherapeutic drugs give full details of the physical and chemical characteristics of the different preparations. A section on the use of hormones develops into a discussion of their use in any gynæcological condition fortuitously associated with cervical lesions. Other therapeutic measures described range from the commonly accepted tampons, pessaries, and douches, through intracervical pencils (which are condemned) to methods to which the British reader may not be accustomed—e.g., cervical massage, artificial pyrexia, thermal baths, radioactive waters, and dietetic régimes. There are good chapters on the use of high-frequency currents, including diathermy and coagulation; and here, with his passion for thoroughness, Dr. Durel even includes circuit-wiring diagrams. Conisation by cutting wire is not discussed at all, and the actual cautery and electrocautery receive scant mention. Hysterectomy is only discussed in so far as it is necessary for chronic adnexal disease.

If Dr. Durel intended to cover all current knowledge on appearances, bacteriology, and methods of treatment of cervicitis he has achieved his object; but his chapters are apt to be watertight, and fail to link up appearances, ætiology, and treatment. Only very rarely does he express a clearcut personal opinion on the value of the various treatments.

Child Psychiatry

(2nd ed.) LEO KANNER, M.D., associate professor of psychiatry and of pediatrics, director, children's psychiatry service, Johns Hopkins University and Hospital, Baltimore. Springfield, Ill.: C. C. Thomas. Oxford: Blackwell Scientific Publications. 1948. Pp. 752. 45*s.*

THE second edition of one of the earliest attempts to present child psychiatry systematically is an important event, the more so as the psychobiological school at Johns Hopkins has seemed to many to provide the most "sensible" approach to this controversial subject. In his effort to be comprehensive, even at the expense of depth, Professor Kanner summarily dismisses psychoanalysis, thus (some will feel) discarding any serious examination of the dynamics of the situations he describes. While he gives a balanced account of the influence of heredity, he interprets the psychological disorders of childhood in terms of crude environmental influences, and the profit motive in the child. Even with such a self-imposed limitation, his choice of a purely symptomatic classification is hard to understand, being at odds with the psychobiological appeal, made early in the book, for a holistic approach to the physical, emotional, intellectual, and environmental problems of childhood. It is difficult to preserve the holistic perspective when, in a section entitled Problems of Behaviour, children are sorted out according to symptoms, under the headings of anger, fear, anxiety attacks, and hypochondriasis. In strong contrast to his appeal for unification are his references to the child psychiatrist's natural allies—parents, school-teachers, hospitals, and juvenile courts—which, on the whole, are unfriendly and even sarcastic; while the work of the psychiatric social worker is dismissed in two pages of vague description.

Professor Kanner's critical qualities, ably displayed in comparative studies of the contributions of others, seem to vanish before deeper psychological phenomena. Since his book will inevitably be in demand among was some elevation of temperature on the first day, a sort of hesitation for another day or two, and then a precipitous fall, as can be seen from the following 6 cases:

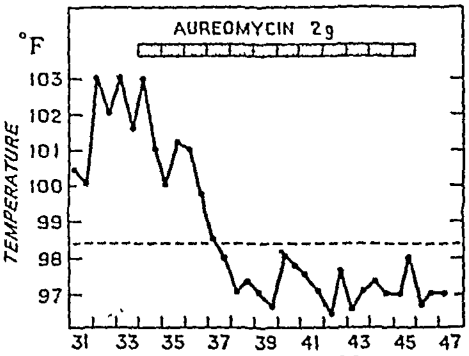

Fig. 4—Effect of aureomycin in case 4.

Case 1.—A woman, aged 47, was admitted to hospital within eleven days of the onset of a very severe "malignant" infection, with toxæmia, delirium, congestion of both lungs, blood-stained *sputum*, albuminuria, and peripheral circulatory failure. She reacted favourably and promptly to aureomycin (fig. 1). Brucella, present in the blood before treatment, disappeared after treatment with aureomycin 2 g. daily for eight days. There was a relapse four weeks later. Blood-culture was again positive, and there was a wave of pyrexia lasting fourteen days, after which the patient recovered spontaneously.

Case 2.—A boy, aged 11 years, with the "undulatory" type of infection, had already had two waves of pyrexia lasting about fourteen days each. Treatment was begun with four capsules (1 g.) daily; but, since the response was not well marked, the dose was increased to 2 g. after two days, after which the temperature came down precipitately (fig. 2). A relapse four weeks later was successfully treated treated with a fuller course.

Case 3.—A man, aged 48, husband of case 1, also had a very severe infection. He was given 24 g. of aureomycin in twelve days (fig. 3). There was no relapse, and the patient was back at work within three weeks of admission to hospital.

Case 4.—A woman, aged 20, with the undulatory type of brucellosis, was in the middle of a wave when aureomycin was started. There was a prompt and satisfactory response (fig. 4).

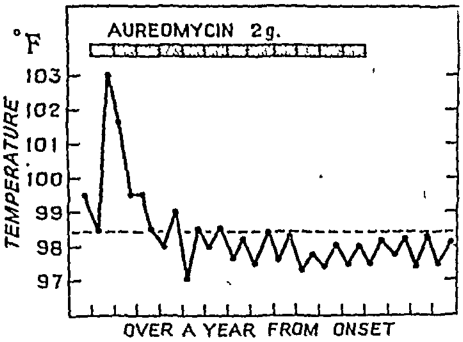

Fig. 5—Effect of aureomycin in case 5.

Case 5.—A woman, aged 24, had had undulant fever for over a year. Her temperature had been subfebrile throughout, with occasional pyrexial waves. Her spleen was enlarged and hard. Blood-culture was positive before treatment. Note "spiking" at the beginning of treatment (fig. 5). After a course of aureomycin, blood-culture was negative and the temperature remained normal.

Case 6.—A woman, aged 28, had been ill for six weeks. Blood-culture was positive before treatment. After a preliminary hesitation, her temperature came down rapidly and has remained low.

The fall in temperature was often preceded by an improvement in the general condition, a clearing of the pulmonary congestion, and an increase in appetite, and was followed by a more gradual reduction in the size of the spleen.

In the first part of the experiment, which included 14 cases, treatment was continued for eight days, and the average total dose of aureomycin was 16 g. Since the supply of aureomycin was so limited, and the of patients clamouring for it so great, it was that this would be sufficient. This economy, proved to be a mistake, and 4 of the cases In 1, a very chronic case of 18 months' duratio plicated by spondylitis and abscess formation, and the fever reappeared ten days later. In the there was a relapse after four, five, and seven In the second part of the experiment treatment from twelve to fourteen days, and so far (minimum of observation is eight weeks) there have been no in the 10 cases.

An important and pleasing feature is that patients treated with aureomycin have been fr the rheumatism which so often complicates th valescent stage and can be as troublesome as the In 2 cases where rheumatism was present before ment (a case of coxitis and another of sacro-iliac with unmistakable radiological changes) the pa eased almost at once and recovery was greatly ac

The blood was cultured immediately after the ment in all cases. It was sterile in all except the boy aged 11 years, whose treatment had been with 1 g. a day.

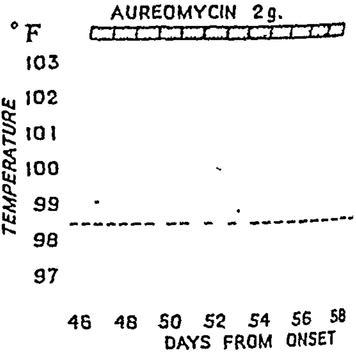

Fig. 6—Effect of aureomycin in ca

This boy relapsed after five weeks and received a second and fuller course of aureomycin without developing any allergic reaction and with a completely satisfactory result. Blood-culture was repeated at intervals of three or four weeks, and the are still being kept under observation in the out *department. In case 1 the brucella reappeared* occasion of a relapse four weeks after the end first treatment. In the other 2 relapses the blood remained negative.

The agglutination titre continued to rise i cases where it was low. The erythrocyte-sedime rate behaved erratically, as it does in untreate The leucocyte-count improved rapidly from the be and in most cases the leucopenia had disappeared four weeks. There was no evidence of any des of blood or aplasia, and the red cells and hæm returned to normal with the improvement in the condition.

So far as one can judge from the limited nu cases, there was no difference in response recent and old infections. Curiously enough th that relapsed included the oldest and the most infections.

CONCLUSION

After a long and disappointing experience treatment of undulant fever one cannot help somewhat *cautious in expressing* one's opinion. withstanding this, the results have been so co so rapid, and even dramatic that it is imposs deny that aureomycin has a specific action on *melitensis* in vivo. It is too early to say whethe eradicate the infection completely and for all tim cases, but it is certainly the only effective re have used so far. The failures can be attrib [illegible] and much work remains to [illegible] dose. It may also happen th strains of brucella may become resistant to aure

RATIONALISATION

The arrangement by which our penicillin is made available to the medical profession through seven well-known pharmaceutical houses, each with its highly organised distribution facilities, is a good example of rationalisation in industry.

We at Speke are kept informed by our distributors of the needs of the profession and are constantly aware of our responsibility in supplying drugs of a high purity and potency.

BAYER

Re-introducing
'PHANODORM' CALCIUM

Brand of CYCLOBARBITONE CALCIUM

'PHANODORM' CALCIUM has been introduced for those patients who find the hypnotic action of 'Phanodorm' itself quite satisfactory, but the onset of sleep delayed. The calcium salt appears to be more rapidly absorbed, quickly inducing sleep which may be deeper than with the original preparation. In spite of this, "hangover" is conspicuous in its absence.

Packings: tubes of 20; bottles of 50, 250, and 1000

students, psychiatrists in training, and pædiatricians, they should be aware that the superficial "common sense" approach may mask an underlying poverty of inquiry into causation. We still cannot predict confidently that a particular type of reaction will be shown by a known child in a given set of circumstances; nor do we know why a certain child falls ill in one way while another child of comparable antecedents, subject to similar environmental influences, will react differently. The elucidation of these mysteries is a task of paramount importance to child psychiatrists of all schools.

Where there is little inquiry below the surface, treatment methods must rely on manipulation of the environment alone. This book, painstaking and thoroughly readable though it is, leaves too many questions open; and induces a mood of disappointment.

Sex in Social Life

Editor: SYBIL NEVILLE-ROLFE, O.B.E. London: Allen & Unwin. 1949. Pp. 506. 21*s*.

THIS symposium on the sociology of sex was ready for the press at the outbreak of war, and now appears in a revised form. Of the experts who contribute, those whose concern is with the scientific background are most at their ease, Dr. C. H. Waddington on sexual biology and Dr. M. Fortes on comparative anthropology being outstanding. In the sections dealing with hygiene and ethics, one occasionally longs for the horse-sense of certain other works. There are passages in which insufficient citation of evidence and confusion of fact with opinion diminish the authority of the writers, but in general the standard is high, though not equal to that of at least one recent American symposium. In books of this kind, the intended audience must at all costs be kept in mind; and to describe *Trep. pallidum*, for instance, as "a worm-like organism," or to state that venereal diseases are commonly contracted without promiscuity, though safe enough in the presence of a trained audience, is to court definite risks in public hygiene teaching. It would, however, be ungenerous to carp at a book which many will find informative and helpful, and which represents a sincere attempt to state the scientific background of a rational sexual ethic.

Progress in Allergy

Vol. II. Editor: PAUL KALLOS. Basle: Karger. 1949. Pp. 356. Sw. fr. 36.

THE first volume of this work appeared before the war under the editorship of Paul Kallos. The second volume resembles the first in having many contributors, but differs from it in being mainly in English instead of German. Since the editor has allowed each author to express his own views, there is not always absolute agreement. They discuss the immunological, chemical, and therapeutic aspects of recent advances in allergy, using the term in the sense given it by von Pirquet.

G. L. Waldbott surveys the ætiological causes of urticaria. He points out how difficult it is to determine the cause in many cases, especially when it is the residue of a long-persisting serum-sickness in which there are none of the usual landmarks of allergic disease. Drug sensitivity (e.g., aspirin) is common in the non-reactor group; but not everyone will agree with his assertion that pollen is as important as food as a cause of urticaria.

F. A. Simon's experimental evidence of the sensitivity of patients to human dander may throw light on the problem presented by the infant with eczema or seborrhœa. It is difficult to know where experimental findings can fit in with the clinical picture, for it was shown that a patient could have positive skin-reactions and circulating reagins for an allergen present in the epidermis of her thigh and her own scalp. Even a newborn infant has allergens in the epidermis. Scratching may therefore be harmful not only because it causes trauma, but also because it favours auto-inoculation.

Professor Haxthausen, too, suggests that the exacerbations of eczema may not be due primarily to antigen-antibody reactions but may be secondary to irritation and scratching. Positive skin-tests of urticarial type are often found in eczematous patients; yet it is urticaria or asthma and not eczema that results from an overdose of the an difficulty is that there are many causes, known an specific and non-specific, which influence an allergi

Animals may be sensitised to bacterial antig tuberculin type or show an immediate response t products like brucella polysaccharide. Dogs, lil can as easily be sensitised to ascaris antigen; but F. who reviews the subject of allergic diseases in a the first to demonstrate spontaneous allergy (a dog which had seasonal hay-fever.

Foster Kennedy postulates that the den diseases, including disseminated sclerosis, have an antigen-antibody upset. Many cases of transien retrobulbar neuritis, peripheral-nerve involveme headache, and migraine, and some cases of epileps with symptoms of an oversensitiveness to prote

E. A. Kabat epitomises the recent advances i chemistry; and aerosol, bronchoscopic, and ant therapy are well summarised.

One small criticism of this valuable w justified. The publishers have not allowed for each reference, and it is most difficult the non-alphabetical jumble which appears of most articles.

Kayne, Pagel, and O'Shaughnessy's I Tuberculosis

(2nd ed.) Editors: WALTER PAGEL, M.D.; SIMMONDS, M.D.; N. MACDONALD, M.D.; F.R.C.S. London: Oxford University Pr Pp. 720. 63*s*.

THE new edition of this textbook is inscri memory of two of the original authors, D Kayne and Mr. Laurence O'Shaughnessy, died since the first edition appeared ten year revising it, Dr. Pagel has been assisted Simmonds, Dr. MacDonald, and Mr. Fatti.

Recent work has made it necessary to alte considerably, and the book is 160 pages long predecessor. It is a sound account of mode and practice, and carries a good bibliogra arrangement remains the same, under the h pathology, diagnosis, prognosis, management all aspects of treatment), and epidemiology a tion. Two appendices cover classification present state of knowledge of streptomycin chemotherapeutic agents. The section on which includes the evolution of tuberculosi occupies considerably more space than any oth but the account is so detailed, well docum beautifully illustrated that the lack of balanc forgiven. Modern methods of diagnosis described, though the statement that inspec reveal a pronounced emphysematous ches not have been made without qualification. T forms of collapse therapy occupy many l accounts of immunisation with B.C.G. and the v form an important part of the section on l The authors urge the need for a clean milk rural areas but claim that the building up of negative herds on a large scale is impract Denmark and the United States, however, it l been accomplished.

An Introduction to Medical Psychology

L. ERWIN WEXBERG, M.D., director, bureau hygiene, District of Columbia. London: Medical Books. 1948. Pp. 171. 17*s*. 6*d*.

THE eclipse of Alfred Adler's "individual ps seems to have prolonged itself sufficiently to b as extinction. Dr. Wexberg, however, shov series of lectures delivered to medical stuc Adler's theory of dynamic psychology can into a body of teaching which takes accoun points of view and more recent studies. contains six chapters—ranging from Indiv Community to Methods and Techniques Psychology—and will commend itself to dislike psycho-analysis but want something from psychology which they can call medical ps inevitably they get something respectable. fashioned.

THE LANCET

VDON: SATURDAY, AUGUST 20, 1949

Mind and Brain

LY there have been several fresh attacks on ennial problem of the brain-mind relationship. s organised by the B.B.C., which produced in rd Programme a series of talks on the Physical f Mind. To Sir CHARLES SHERRINGTON, who the discussion, the physical changes in the nd the mental phenomena which accompany re separated by a gulf that seems at present geable. "It is a far cry," he said, "from an al reaction in the brain to suddenly seeing the around one, with all its distances, its colours aroscuro. . . . ARISTOTLE, 2000 years ago, was how is the mind attached to the body. We are that question still."[1] Prof. E. D. ADRIAN was ır from optimistic about our prospects of ing the relation between the brain and the "The real trouble," he said, "comes from the that there may be an important part of ture which can never be fitted in, however long y work at it."[2] An anonymous neurologist,[3] er, was hopeful that new knowledge might from a parallel advance in physiology and logy. He pointed out that a rat can be trained gnise a triangle and to distinguish it from a or circle. Such a rat, therefore, may be said ware of triangularity. This implies a process in rvous system by means of which a rat recognises igle and which is of the same kind as that by a human being recognises a word. This neural s, common to both animals and man, is the of abstract thought. The neurophysiological ation of speech and thought can be interpreted n terms of electrical patterns in the nervous n organised both in space and time, and comnsion of the brain-mind relationship will when we can understand the part played by patterns. If one looks at a tapestry through a ifying-glass one sees the individual threads but e pattern: from a distance one sees the pattern t the threads. He suggested that in the nervous n we are looking at the threads, while with the we perceive the pattern, and that one day we discover how the patterns are made out of the ds.

e series concluded with the contributions of three sophers,[4] Lord SAMUEL, Prof. A. J. AYER, and GILBERT RYLE. Lord SAMUEL, who accepted ualist hypothesis, had to admit that he saw no ion of the problem. Professor AYER's solution was y that the problem does not exist, or, at least, it is merely the product of the terms we use. The iologist's story is complete in itself: so, too, is the psychologist's. But they will not mix. "Each is an interpretation of certain phenomena and they are connected by the fact that, in certain conditions, when one of them is true, the other is true also." His conclusion was "that mind and body are not to be conceived as two disparate entities between which we have to make, or find, some sort of amphibious bridge, but that talking about minds and talking about bodies are different ways of classifying and interpreting our experiences. . . . Once we are freed from the Cartesian fallacy of regarding minds as immaterial substances, I do not think that the discovery of casual connexions between what we choose to describe respectively as mental and physical occurrences implies anything by which we need to be perplexed." Here Professor AYER seems to be adopting a materialistic monism and to imply that the physiological and the psychological are two different ways of looking at the same thing, from without and from within as it were. Professor RYLE also appears to be a monist since he complains that the difficulties all arise from the attempt to explain human behaviour in terms of the two entities mind and matter. Everything would be much simpler, he thinks, if both these terms were dropped.

This series of broadcast talks aroused wide interest and had educational and possibly even entertainment value. They were not perhaps very likely to go much further than ARISTOTLE. Like a somewhat uncoördinated attack on a wide front between allies speaking different languages and using dissimilar weapons, the engagement resulted in no striking advance. The physiologists and neurologists may, indeed, have been left with the feeling that the philosophers evaded the issue; for even if the whole problem is a matter of terminology, this statement does not really make it any easier for us to understand the relation between one experience, which perhaps wrongly we term physical, and another to which we erroneously apply the epithet mental.

N. WIENER has invented the term cybernetics[5] to describe the study of those problems he believes to be common to certain electrical machines and the nervous system. The development of electrical computing and statistical machines has led to the discovery that such machines are able to perform many tasks of which hitherto the human mind alone was thought to be capable. If the machine and the brain carry out these performances in fundamentally the same way, the machine may throw light on the organisation of the nervous system. At a comparatively low level, self-regulating mechanisms, such as the feedback, which are utilised in mechanical as well as in electrical machines, seem to be paralleled in the nervous system by the processes which regulate and graduate voluntary movement and which are manifestly disordered in patients suffering from tabes dorsalis or from lesions of the cerebellum. At a higher level the machine can be constructed so as to possess something equivalent to memory and to be capable of acts of abstraction which generate something which finds a mental equivalent in an idea or a universal. WIENER is careful to say that the mechanical process is not necessarily identical with the cerebral process, but that the machine's performance is a model of

An absorbable hæmostatic

Gelatin Sponge A&H may be used to control hæmorrhage when ligature is inadequate or impossible. It hastens the normal clotting mechanism, provides support for the blood-clot, and does not retard the process of wound repair. It is completely absorbed without foreign-body or antigen reaction, and it does not inactivate penicillin or streptomycin.

Gelatin Sponge A & H provides an effective hæmostatic for use in many surgical procedures ranging from the first-aid treatment of surface wounds, especially those involving large veins, to the control of operation hæmorrhage from oozing surfaces or of massive hæmorrhages when the bleeding-point cannot be easily identified.

By minimizing blood loss, the use of Gelatin Sponge A & H will increase the safety, and may widen the scope, of operative surgery in many fields.

mustard in prolonging the life of mice with phoid leukæmia AK4. This effect was seen hen the drug was given in the maximum d doses and was about the same as that ig treatment with 4-amino N^{10} methyl- glutamic acid. (This latter compound is an ic-acid-drug which may be more active than terin.) Lately a new purine antagonist has und by study of the nutrition of *Tetrahymena* micro-organism which requires both guanine acil for growth. Experiments showed that o-7-hydroxy-1-H-v-triazolo-[d]pyrimidine. is called guanazolo because it is a guanine ıe, is a powerful inhibitor of the growth of ganism. Guanazolo was tested in mice and to inhibit the growth of a rapidly growing anted adenocarcinoma.[7]

study of growth inhibitors analogous to natural onstituents has thus led to the discovery of al compounds which are at least of interest palliative treatment of leukæmia and cancer. ne of investigation is being followed and may the discovery of drugs of real clinical value in ant disease.

Cobalt and Red Cells

idea that some of the less common metals nportant in erythropoiesis is one that has ared at intervals for many years. It was ntly invoked to explain the occasional failures n to restore a normal blood-count; but we now that, in man at least, the true explanation ally poor absorption from the alimentary tract haustion of iron stores in the body. **Elvehjem**[8] is co-workers demonstrated that in rats, made ic by living only on milk, hæmoglobin would rate more rapidly on a mixture of iron and r than on iron alone: but no similarly convincing ıce has ever been produced to show that the of hæmoglobin regeneration in human iron- ncy anæmia improves if, in addition to iron, ve copper, manganese, nickel, or molybdenum, often recommended.

case of cobalt is different; for cobalt deficiency own to be responsible for an anæmic disease of and cattle in various parts of the world (described bush sickness" or "enzoötic marasmus"), and also known that in animals cobalt salts can e a polycythæmia largely due to an increase mass of circulating red cells. Thus **Wintrobe** ıis colleagues[9] gave cobalt salts to rats which developed anæmia after sterile injections of ntine had been used to produce a local inflam- n: not only was the anæmia abolished but of the rats became polycythæmic. On the hand evidence about cobalt as a stimulator ıman erythropoiesis has been little better than about other related metals, and it is therefore esting to have some further information about its n in man. In 1947 **Weissbecker** and **Maurer**[10] ted the results of giving a daily dose of 500 mg. baltous chloride by mouth to normal subjects: all showed a reticulocyte response, which was followed by increases in the red-cell count, the hæmoglobin, and the circulating red-cell mass: but doses of this order proved unpleasantly toxic. **Robinson, James**, and **Kark**[11] have now studied the effect of long-continued oral administration of cobalt to 9 patients with chronic sepsis—patients who had been injured by war explosions or in car accidents. They used much smaller doses (20–60 mg. daily of cobaltous chloride) and gave them for two to eleven weeks. None of the patients had severe anæmia: the lowest count was 3,420,000 red cells per c.mm. with 11·0 g. hæmoglobin per 100 ml.: none were given any other form of hæmatinic treatment, but all were well fed —by American standards. A reticulocyte response not exceeding 5% occurred between the sixth and tenth day, and thereafter the patients, with one exception, showed increased red cells, hæmoglobin, and circulating total hæmoglobin; in the cases quoted, where the patient had 60 mg. daily for four weeks, the red cells rose to 5,190,000 per c.mm., the hæmoglobin to 13·5 g. per 100 ml., and the total circulating hæmoglobin from 470 to 670 g. The only untoward symptom was slight loss of appetite in 2 patients. Of a larger group of similarly affected patients who were watched as controls, none showed increases in blood values while the suppuration persisted.

Berk, Burchenal, and **Castle**[12] have approached the problem differently. They first gave cobalt to a group of 17 convalescent patients who were not anæmic. By experiment, the most effective dose was found to be 300 mg. of cobaltous chloride by mouth, on which most of the patients showed a reticulocyte response about the tenth day, with a rise in red cells and hæmoglobin. The only evidence of toxicity was loss of appetite, but the red cells of one patient who had been treated for eleven weeks rose to nearly 7 million per c.mm. and it was considered advisable to reduce this by venesection. Previous reports having been thus confirmed, they went on to observe the effect of this dose in 32 patients with anæmias that were refractory to the usual treatment—most of them secondary to leukæmia, nephritis, or other conditions. The results were mainly negative: it was particularly disappointing that 5 patients with primary refractory anæmia and a hypercellular bone-marrow showed no response at all. Of 5 patients with anæmia associated with chronic infection, 2 showed a rise in blood values after four weeks. The only notable success was in a leukæmic patient receiving nitrogen-mustard treatment who after two months' cobalt therapy responded much better to blood-transfusion. After this experience the investigators are understandably cautious about the value of cobalt in the treatment of anæmia. They think that in chronic infections the benefit accruing from a rise in hæmoglobin may be offset by the loss of appetite. They see no indication that cobalt is useful as an adjuvant to iron or liver treatment, and their observations on pernicious anæmia suggest that in patients with achlorhydria it may give rise to serious symptoms.

There is reason to think that cobalt acts by forming oxygen-binding complexes with amino-acids such as

the way in which the brain may possibly work. Whether we should call the new point of view materialistic, he said, is largely a question of words: "The ascendancy of matter characterises a phase of 19th-century physics far more than the present age, and 'materialism' has come to be but little more than a loose synonym for 'mechanism.' In fact, the whole mechanist-vitalist controversy has been relegated to the limbo of badly posed questions." In this he seems to agree with Professor AYER.

A remarkable book[6] has just been published by ARTHUR KOESTLER, hitherto better known as a novelist than as a writer on neurology and psychology. "Artists treat facts as stimuli for imagination," he writes, "whereas scientists use imagination to coördinate facts. The aim of this book is, first, to show that such distinctions are not fundamental, that all the creative activities of man are based on a common pattern, and to present a unifying theory of humour, art and discovery, in which these are shown to differ merely in degree and not in kind. Secondly, the attempt is made to show the possibility of a system of ethics which is neither utilitarian nor dogmatic, but derived from the same integrative tendency in the evolutionary process to which the creative activities of art and discovery are traced." KOESTLER begins with an analysis of the nature of the comic. Laughter, he maintains, whatever its immediate cause, is always the result of the intersection of two planes of experience. From the simplest pun to the most complex humorous narrative there is always a double entendre. In this he was anticipated by HUGHLINGS JACKSON who described punning as "mental diplopia." KOESTLER calls this intersection of planes of thought "bisociation," and he explains that "the abrupt transfer of a train of thought from one operative field to another leads to its separation from its original emotional change." In this connexion he discusses the neurophysiology of emotion and points out that "emotional processes have a greater inertia than cognitive processes." It is this that renders a psychophysiological discharging process biologically valuable. Thus a "self-transcending" line of thought may discharge the emotion generated by an aggressive impulse. This leads to an analysis of the social aspects of these impulses in a society which gives insufficient scope to self-transcendence. Finally, he applies his theory to the creative impulse in scientific discovery and in art, and accords to art a special rôle in providing occasions for self-transcendence.

This age suffers from having a culture which is literally incoherent, because it is divided into specialties that so far are largely unrelated to each other. KOESTLER's theory may at times be over-simplified: this volume in any case is introductory, and a second is promised. His great virtue, however, is that his philosophy is integrative. The value today of a bold attempt to bring together thought and feeling can hardly be overestimated. In addition, he uses neurology and psychology to illuminate each other. Both these syntheses are contributions to the new renaissance—that rebirth of a comprehensive system of thought in which the present generation has to play the painful bisociative part of mother and child, fire and phœnix.

Growth-factor Analogues in Cancer T

THE hypothesis that some therapeutic
by competitive inhibition has been widely
during the last ten years and has been th
point of searches for new remedies for ba
protozoal infections. It is therefore not
that growth-factor analogues should be
activity against cancer. An early examp
investigation was the use of malonic acid—
product of the intermediary metabolism of
hyde and a known inhibitor of succinic deh
—which was found to retard the growth of s
mammary cancers in mice.[1]

The recent extensive work on pterins re
with the observation that, whereas naturally
folic acid inhibits the growth of cancer
synthetic folic acid has no inhibitory ac
difference was shown to be due to pol
pteroic acids, such as teropterin, which
interfere with the action of folic acid (mo
pteroic acid). Though teropterin proved
against cancer in man, other derivative
amethopterin (a methyl-folic acid) and an
(4-amino-pteroylglutamic acid),[3] have give
ting results in the treatment of acute

dency of Prof. Gunnar Holmgren. The trans- of this conference, which have recently been l as a supplement (no. 76) of the *Acta Oto- gea,* include a survey of the present status of in the United States, international standards metry, and the relation between otology and A short account of the second conference, is held last month in London, is given on p. 356. intended that this conference should, in any e over the work of existing professional bodies, ponsors hope that it will continue as a means of together, quite informally, all scientists who are d in hearing, deafness, and speech. The rapid made in recent years in electro-acoustics and nedical and surgical management of deafness is believed, best be consolidated through an tion that already comprises workers from more een different countries.

knowledge of electro-acoustics has turned us vorld of listeners; and whether we listen for ment, for entertainment, or for want of some- tter to do, good hearing and good hearing condi- of greater moment to us all, in our everyday n ever before. It is estimated that not less than e population are hard of hearing and, in addition, n be but few who do not sometimes wish that stic quality of what they are listening to could be d. Audiology, then, though it may be a new not a new science, but rather a means of bringing scientists with a common interest in hearing— ct that concerns us all. As such, it deserves port.

THE WAY THE MONEY GOES

ES being the season of mellow fruitfulness these the days of reckoning. Finance is in the air, ide and outside hospitals the question is being how the accounts for large bodies entrusted with noney can best be kept. Last year the Public ts Committee suggested that the Government's ture on universities and colleges might more iately be covered by statutory authority than Annual Appropriation Act. The Treasury that there were strong reasons against this, nted out that it had never been "the policy of any ment that the universities should be subject to y regulations or that academic policy should trolled by the State." Furthermore, academic ds on the maintenance of which grants must d, are hardly susceptible of statutory definition, n a formula be easily devised which would tically measure the help needed. The uni- s themselves were apprehensive of any encroach- n their present position, and the Government tisfied that the present arrangements reconciled ity autonomy with the need to safeguard public

In their report for 1948–49, which has just ed,[1] the committee admit that they are impressed e arguments. But there are no detailed accounts increasingly large sums involved—the universities over £17½ million this year as compared with der £12½ million last year—and the committee hat the Treasury will consider whether, without ng the independence of the universities, further can be suggested to assure Parliament that the are wisely used.

committee also considered the finances of eleven ided bodies ranging from the Arts Council of Britain to the Medical Research Council. They whether the time has not come when these should be converted into ordinary departments to normal Parliamentary control. If it is wished ntain their independence for the time being, the ttee recommend that their accounts should be made more informative. It should, for instance, be possible to compare the estimate for each main item of expenditure on which the provision for the grant is based with the figures in the account. The Treasury agree that there should be no difficulty in arranging this.

The tendency for Government assistance to dry up voluntary financial effort is noted with regret. "The degree of Government control must depend on the proportion of Government grant to total income, and the independence of these bodies, which is itself one of the main justifications of the grant-in-aid system, must be impaired if they are wholly or mainly dependent on Government grants." The committee therefore suggest that voluntary subscriptions should be stimulated either by limiting the duration of these grants or by making them proportionate to the subscriptions forthcoming. To spend money wisely is never as easy as it appears, and this report adumbrates some of the peculiar difficulties of spending public money. But the independence of our universities and scientific bodies has a value that is not shown in a profit-and-loss account, and money is not always best spent when we know most clearly what it has bought.

BILHARZIAL FILMS

BILHARZIASIS is one of the most serious debilitating chronic diseases, widely endemic throughout the more populous parts of Africa. Yet few educational films for doctor or layman have been made describing the disease and its ravages. The more welcome are two new films prepared for the government of Southern Rhodesia, which had their première in England before a distinguished audience at the London School of Hygiene and Tropical Medicine on June 30.

Vesical schistosomiasis has been known to exist in Egypt since 1200 B.C.; but not until 1851, when Professor Bilharz, who then occupied the chair in zoology at the University of Cairo, discovered the parasite in human cases was the cause of the disease made known. Another 65 years passed before Professor Leiper made clear the remarkable channels and stages in the life cycle and development and in the transmission of the parasite from man to man. It was in 1915 too that specific treatment for bilharziasis with antimony was first discovered. Epidemics of bilharzial hæmaturia affected Napoleon's troops in Egypt, British troops in the South African War, and Empire soldiers serving in various parts of Africa in the 1914 and 1939 wars. Recent estimates of the incidence of bilharziasis among civil populations indicate that half of the population living in the lowest and widest parts of the Nile Delta suffer from *B. hæmatobium* infestation. Although Egypt is the most severely affected country in the Middle East the disease has also been recognised in the past 50 years among the inhabitants of villages bordering the Tigris and Euphrates 900 miles from the mouths of these rivers. In 1918 the disease was first found to be endemic in parts of Palestine and in 1922 in Syria. Forty years ago the importation into Southern Rhodesia of large numbers of African labourers from the northern parts of the continent resulted in widespread infection of the planorbis snails in the local rivers, with a spread of bilharziasis among the native population. Now a fifth of the population of Southern Rhodesia is believed to be infected with bilharzia. The Schistosomiasis Research Laboratory at Salisbury has long been engaged on the problems of mass diagnosis and treatment of the disease among the populace of Southern Rhodesia. Pioneer papers from this laboratory, on intensive antimony and on 'Miracil D' therapy, have appeared in these columns.

The African Schistosomiases was prepared under the medical guidance of Dr. D. M. Blair for showing to doctors, and this no doubt accounts for the excellence of the photomicrography of the parasite and tissue histology and for the extremely well pictured and

histidine and cysteine. Experiments on animals[13] have shown that such complexes are *relatively stable* in the body, and they may act by creating an anoxia in the bone-marrow. The response to such anoxia is known to be just what is observed after treatment with cobalt—i.e., increases in the red cells and hæmoglobin of subjects who are not anæmic. In anæmia the stimulus of anoxia already exists, so cobalt has little or no further effect.

Interest in cobalt has been further aroused by the discovery that it seems to be a constant constituent of vitamin B_{12}—one of the substances that can transform megaloblastic erythropoiesis to normoblastic. In view of the anæmia known to be caused in cattle and sheep by cobalt deficiency, it was natural to suggest that the animals were suffering from a deficiency of vitamin B_{12}, possibly because their intestinal flora could not synthesise B_{12} in the absence of cobalt. This hypothesis has been tested by BECKER, SMITH, and LOOSLI.[14] It was known that cobalt deficiency in lambs can be cured by them with as little as 1 mg. daily, but that cobalt is *injected* no detectable response o as long as seven weeks, presumably because th does not reach the rumen in sufficient quan this syndrome were really a B_{12} deficiency, of vitamin B_{12} should produce a remission. dingly, lambs with conspicuous symptoms o deficiency were injected with crystalline vit in doses of up to 125 μg.; but the sympto unaffected. Vitamin-B_{12} concentrates were to affected lambs for up to six weeks; but a results were negative.

We are left with the impression that, cobalt deficiency is of real importance in it plays no part in physiological erythropoiesis Its action on the red cells of normal or mildly persons seems to be a kind of artificial stin and the therapeutic value of such stimul syndromes that are essentially deficiency must be very limited. There are usually more means of attaining the desired result.

Annotations

THE HOUSE COMMITTEE

THE larger the group of hospitals under a single hospital management committee or board of governors, the greater is the need for each of them to have a house committee to study its particular needs. Many such house committees have been set up, their official status being that of subcommittee to the [illegible] mittee itself; but their constitution, [illegible] allotted to them, vary widely. In discussing these functions last October[1] we remarked on the risk that if too much power was delegated to the house committee the result would be administration in three tiers—regional board, management committee, and house committee—instead of the intended two. But we also urged that house committees, as "the people on the spot," must have real authority if they were to be of any use. We suggested that their primary responsibility might be defined as "to make recommendations to the hospital management committee on all matters affecting the welfare of the hospital."

While accepting the propriety of local variation, the Ministry of Health has now laid down some principles that it believes should be followed henceforth. The Minister holds that "in large or widely scattered groups the appointment of house committees can do much to stimulate and maintain a lively local interest in the hospital service, to give valuable opportunities for voluntary public work, and to provide a field for recruitment, or a training ground, for future members of management committees and boards of governors." In some areas (though the Ministry does not say so) the idea of having house committees has been attenuated almost to futility by confining their membership to a few members of the management committee itself, meeting with all the usual officers. Reminding them that subcommittees need not all be drawn from the parent committee or board, the Ministry advises that local organisations should be consulted in making a choice of people to be coöpted, and points out that retiring members of boards and committees need not be excluded.

On the vexed question of their purpose in the scheme of things, the Minister thinks it undesirable to confer executive functions on house committees—e.g., to delegate to them powers of appointing staff, or of incurring expenditure (other than from "free moneys.") Their value, the Ministry says, lies rather in over daily conduct of the hospital and the welfare of and staff, and of making recommendations to the ment committee or board of governors for tho to decide. Accordingly the powers delegated should never exceed the following:

General.—(i) Visiting, supervising the *welfare* of and staff, and making recommendations to the m committee or board on the day-to-day running of th (but not taking executive action). (ii) Reco developments or new policy to the management c or board.

Financial.—(i) Managing the individual hospit of the management committee's or board's "free (House committees cannot, however, legally accep gifts. These must be held in the name of the ma committee or board of governors). (ii) House c should not, however, be empowered to incur on authority any expenditure from Exchequer funds.

The policy thus set out by the Ministry, if in positively rather than negatively, should go far house committees with a life which some now lack. There is a very real need for lin hospitals closely with the local communities th and with care and wisdom the house commi be made into a strong link rather than a weak

AUDIOLOGY

"The science of hearing" is the definition the new word "audiology" which has lately be to the medical dictionaries. Hearing, and for tha lack of hearing, has been and continues to be of prime interest and importance to the otolo physiologist, the psychologist, the physicist, th tionist and the teacher of the deaf, the phonet the speech-therapist, and the worker in social All these "ists," and more, are concerned with but only too often they have tended to stu isolated groups, concentrating on one of its many and the interchange of information between thes has not always been as free as it might have b provide a meeting-ground where all the pro authorities can pool their problems and the solutions, it seemed that some new organisat needed; and so audiology was conceived.

Already in America there are a professor of a (Professor Cahart) and consultants in audiolog Veterans Administration, the chief of whom Norton Canfield. Last year, the first Inter Conference on Audiology was held in Stockholm efforts in all sorts of fields, in spite of the . of the State in social work since July 5,

ATRIAL INFARCTION

the frequency and great clinical significance tion of the left ventricle is considered, the of the other heart chambers from such lesions rkable. According to Soderström,[1] however, y be much commoner than is thought. Being ss conspicuous than those in the left ventricle, apt, he thinks, to be overlooked. He set out to te infarction of the auricles using autopsy in which there was auricular thrombosis; and ible, incidentally, to study the general ætiology romboses in these chambers. Apart from the in the left auricular appendix, found particularly matic heart-disease and probably caused by gnation of the blood-stream, auricular thrombosis erally due to an underlying lesion—either a mural ditis or a myocardial infarction. Discussing at the relation between auricular fibrillation and rombosis, he concludes that the direct connexion them has been exaggerated. Atrial infarction, is almost impossible to recognise with the naked d even its histological diagnosis proved difficult. id it very much more often in the right than in t auricle, the difference being accounted for, , by the oxygenated state of the blood on the . Clinical recognition of atrial infarction is difficult it causes few signs and symptoms; but cardio- changes may suggest its presence. The P wave abnormal in size or form, and the P-Q interval e shortened; but a more characteristic finding elevation of the P-Ta level, which Söderström as diagnostic of infarction of the posterior wall ight auricle.

APPROVED NAMES FOR DRUGS

ING the late war the General Medical Council from time to time lists of approved non- tary names for foreign drugs which were being, ut to be, manufactured in Britain. The aim was ck the multiplication of names for the same nces, and since the war the British Pharmacopœia ission has extended the practice to drugs devised as made in this country.

ssuing its latest list (see p. 354) the commission s that if any of the drugs given approved names entually described in the *B.P.* these will be their titles, though recognition of an approved name ot imply that the substance will necessarily be ed in the *B.P.* The commission will consider ts from manufacturers and others for approved for products which seem likely to come into ished use. Such a request should be accompanied armacological and clinical reports on the drug ned and several suggestions for a suitable name, ng any that are similar to existing trade marks ther current names. In coming to a decision the ission's nomenclature committee will consult the facturer's representatives, but the final choice will ith the commission. If a manufacturer then issues rug under a proprietary name, the approved name d appear on the label no less conspicuously than proprietary one. The commission sets out the ing principles for guidance in devising new names:

nes should preferably be free from any anatomical, ological, pathological, or therapeutic suggestion.

attempt should first be made to form a name by com- syllables from the scientific chemical name, so as to ite the significant groupings of the compound.

mes should, in general, not exceed four syllables. They d be distinctive in sound and spelling from those already in use. Names which are difficult to pronounce or to remember should be avoided, as should the addition of a terminal capital letter or number.

Names used in the *U.S.P.*, the *B.P.C.*, or in *New and Non-Official Remedies* should receive preferential consideration.

These terminations should be used:

-ine (Latin *-ina*) ..	for alkaloids and organic bases.
-in (Latin *-inum*) ..	for glycosides, glycerides, and neutral principles.
-ol	for alcohols and phenols (-OH group).
-al	for aldehydes.
-one	for ketones and other substances containing the CO group.
-barbitone or -itone .	for barbiturates.
-caine or -aine ..	for local anæsthetics.

Correspondence relating to approved names should be addressed to the secretary, British Pharmacopœia Commission, 44, Hallam Street, London, W.1.

VETERINARIANS AND FOOD-SUPPLY

THOUGH the peoples of many parts of the world go short of food, and the carrying capacity of the soil is being reduced, the population continues to increase, especially in the more primitive areas. As Lord Boyd-Orr pointed out in his opening address to the 14th International Veterinary Congress held in London last week, many scientific developments are tending to accelerate these tendencies. He had great faith, however, in the ability of the agricultural and engineering sciences, if properly applied, to restore many of the eroded soils, and he regarded the activities of the veterinary services as almost wholly beneficial. This is generally true, because when man prevents disease in livestock it enables him to adopt better methods of breeding and management; and he usually does not allow domestic animals to multiply beyond his needs. In a wide survey of the veterinary profession's contribution to the world's meat-supply, Mr. C. S. M. Hopkirk described how vaccines have been used successfully against cattle plague (rinderpest) by UNRRA and later by the Food and Agriculture Organisation. Work on rinderpest and all the other diseases of animals and poultry, together with the study of animal nutrition and genetics, are obviously beneficial; although, when discussing the breeding and rearing of animals, Prof. N. Lagerlof argued that hormonal treatment which permits animals with functional sterility to breed may have its harmful side. These subjects and many others relating to animal production were discussed at the sectional meetings, and the congress certainly did much to stimulate improvement in methods of disease control which will have their eventual effect on the provision of foods for human consumption. At its closing session it recommended strengthening of international veterinary organisation. so as to set up an active world-wide control capable of advising governments on the urgent steps necessary to control animal diseases.[1]

When the British Association meets at Newcastle-on-Tyne on Aug. 31 it will hear a presidential address from Sir John Russell, F.R.S., on World Population and World Food-supplies; and much is likely to be said on this basic subject in the discussions that will follow.

DR. W. G. WILLOUGHBY, formerly medical officer of health for Eastbourne and a past president of the British Medical Association, died on Aug. 13 at the age of 83.

Sir ALAN NEWTON, past president of the Royal Australasian College of Surgeons, died in Melbourne, on Aug. 4, at the age of 62.

On Aug. 11 the Red Cross conference at Geneva voted approval of the four new conventions adopted last year at Stockholm (see *Lancet*, 1949, i, 761). This vote does not, however, mean that all the 60 nations taking part in the conference will ratify all the treaties.

EVENTING RECURRENCES OF RHEUMATIC FEVER

EN a new prophylactic or remedy is discovered,
seldom be accepted and applied until trials have
made with a limited number of patients under
lly controlled conditions, so as to ascertain, for
ple, whether it is likely to produc toxic symptoms or
oke a resistant strain in the causative organism.
is middle stage—between research and general
ation—belongs contemporary work on prophylaxis
umatic fever. The use of sulphonamides for this
se has been under investigation in the United
for over ten years, and there have also been
at three different centres in this country, yielding
s that are understood to be less conclusive. The
from Australia which we publish at the front
s issue describes observations on 211 treated cases
study which began in 1944. Small doses of sul-
lamide were administered daily and continuously
roup of children immediately after acute rheumatic
es, and the recurrence-rate in this group proved
3·2% in 565 person-years, which compares favour-
with 11·8% in 971 person-years in a control group.
figures are comparable to those reported in
ca and summarised by Barclay and King-Lewis,[1]
there was a recurrence-rate of 1·2% in 500 patient-
s in treated cases, and of 19·8% in 500 controls.
fessor Rubbo and his colleagues who did this work
toxic symptoms as "minimal." They demonstrated
evelopment of a sulphanilamide-resistant strain
molytic streptococci, but this did not seem to be
ated with any alteration of virulence or infectivity,
ey therefore think that such a use of a sulphonamide
no eventual danger to the community. Large
h it is, the size of their series, and the period of
ation, are insufficient to prove conclusively that
namides should be used in the prophylaxis of
atic fever. But the harm done by this disease in
g carditis is such that work meeting even with
legree of success deserves close attention. Not
teresting should be the results of research now being
d out in England and America with penicillin as
ophylactic.

Barclay, P. E., King-Lewis, F. L. *Lancet*, 1945, ii, 751.

DANGER IN MONEY

MOST of us have only one complaint about
notes ; but in Scotland[1] they are speculating a
danger of handling them in large numbers. W
bactericidal effect of copper and silver salts is
believed to keep our change relatively safe, paper
has no self-sterilising properties, and bank-n
gather dirt and probably pathogenic bacteria
Nisbet and Skeoch have examined 36 notes of
denominations by rubbing them with swabs mo
glucose broth. From the swabs cultures were
broth and also on tellurite and blood-agar p
the 36 notes 7 were found to be contaminated
or more potential pathogens. Hæmolytic st
were isolated from 2 notes, *Staphylococcus aur*
5, and pneumococci from a £1 and a £5 note. *C*
terium diphtheriæ was not isolated, and no special
was made to recover *Mycobacterium tuberculosis*,
some previous workers have reported both org
paper money. The main source of these pat
of course, the hands ; but respiratory cont
may occur when we sneeze at our pay-packet or
note is stuffed into a pocket containing, or cont
by, a purulent handkerchief.

Nisbet and Skeoch did not estimate the nu
pathogens on each note, but presumably they
small. In banks and pay offices, where large n
notes are handled and finger-tips are often licke
may be more danger. The dust arising during the
of numerous grubby notes, or during the sorting
library books, may be considerable, and, as Nis
Skeoch point out, there should be adequate ven
where such work is done. Disinfection of ban
at regular intervals might be possible, and a
moistened with a suitable disinfectant fluid
comfort the teller. Meanwhile most workers will c
to study the physical rather than the biological
of the wad.

VOLUNTARY EFFORT

IN the wake of Lord Beveridge's *Voluntary*
published last year, comes the evidence[2]—or th
presentable portion of the evidence—on which th
was written. Such a supplementary volume is
ably a collection of scraps, which makes it rather
reading ; but this one was well worth publishing, if
a directory, though its account of some 400–500 vo
societies (all established in a big way) is eclipsed
handbook lately republished by the National
of Social Service. Just as, in *Voluntary Action*
Beveridge was primarily concerned with friendly s
so, in editing the *Evidence*, he gives pride of p
Mass-Observation reports on what large num
ordinary citizens thought about the practice of
aid, and about paying their weekly pennies or s
into a friendly or a collecting society for th
of extra sick benefits and death benefits. One
achieved by these painstaking interviews of
samples is to show that nearly half the people
really understand fully what they were talking
Some were indifferent about whether they paid
into a genuine voluntary friendly society or
collecting business like the Prudential. Others
know the meaning of the term "Friendly Soc
one woman in a northern town thought it was so

an "unfit for work" form or milk-priority ate. Nevertheless, the danger of such influence ification may be equally great on the other side; e State, with its greater powers, can bring more pressure to bear upon a doctor on more important than a private patient can. To take a firm line patient may mean losing that patient. To take a ne with the State may mean losing one's job, or unless the doctor has either a strong assurance of egrity of the State or has his freedom of judgment dequately safeguarded.

tors should make it clear, to themselves and each to the State and local authorities, and to their patients, that they are obliged by their ethical o give an objective professional judgment on s of certification, no matter who is paying them, hat their opinion cannot be altered to suit the yer. This does not, of course, exclude an obligation doctor's part to take a "humane" view, because lso part of the doctor's ethical code to be humane. a hospital board of governors, or a local authority, egional board employs its doctors to treat their ts impartially as fellow-citizens, as "whole men," is well to remember that it is they, and not the ls of the organisations concerned, who are the r's ultimate paymasters and employers. If no e patient has the right to expect indulgences in t of certificates not supported by medical facts, partment of State or local authority has the right nand harshness from the doctor or to permit medical to be ignored. In either situation, the doctor has luty to insist on maintaining the integrity of his ssional opinion.

e other dangerous potentiality is that public policy ertain disputed matters, such as the use of birth ol or of abortion, may clash with the conscientious s of individual doctors. The matter has already n in connexion with certain public-health appoint- s; but the Ministry of Health has always shown a ct for the scruples of the medical officers and nurses erned, and has issued instructions, for example, no persons shall be compelled to give birth-control e as a routine duty. In the Parliamentary debates he National Health Service Act these assurances repeatedly renewed.

RESPONSIBILITIES

is clear, however, that with the "State" in one or another as his main, and perhaps in time as his , employer, the Christian doctor must have a par- arly vigilant eye on his rights and responsibilities elation to it and to his patients. An easy-going iescence in the conditions under which he has to k will henceforward be impossible for him; otherwise nay find that, either through malice or ignorance, ill be made impossible for him to do his proper work. ainly he must not give in to the defeatist notion, h ardent partisans endeavour to foster and which ontradicted by the practice of the large number of tors already engaged in public service, that when he omes the servant of a public body he will no longer d, and in any case will not be able to maintain, high idards of professional behaviour. To say that is ually the same as saying that under the conditions modern technical society he finds it impossible to rcise a Christian vocation at all, because it is as much pressure of the kind of society in which we are all as any overt action by the State which is forcing upon medical profession this much more centralised anisation of its activities. Diligence, courtesy, com- sion, and disinterestedness are certainly not needed in a Government or local-authority officer than they in a general practitioner. In fact they are more needed, ensure that the patient himself is not lost in a mass of red tape, and they will be the more appreciated because they will be known to be freely and spontaneously given. Any organisation is very much what those who run it make it, and doctors, whether they agree with a State medical service in principle or not, should do their best to work it with the utmost determination to make the best of it. If they take a strong and adventurous line it is fairly safe to assume that they will be able to do far more with it than they ever realised. After all, even on the most realistic level, they are not without powerful weapons in their hands to resist attempts to coerce them into doing things which violate their professional code. A courageous readiness to maintain their professional integrity—which always involves courage in a fallen world, whether among doctors or any other section of the community—together with a firm recognition of their conscientious duty to their employers, will do more to establish the best interests of the profession under the new relationship than any unseemly squabbles about fees and petty rights.

This is not to say that under a new régime there will not be a greater need than ever for doctors to have strong professional associations, to guard their liberties and to sustain individual protests. But these associations themselves, if they are to continue to speak with authority and to command the sympathetic attention of the public, must have a wide and imaginative conception of the doctor's vocation. Above all, there should be a clear-eyed recognition on the doctor's part of the vital importance of informed and responsible political institutions. Any body which submits itself to a measure of State control in these days is giving hostages to fortune. Everything ultimately depends on the sort of master the State is likely to be. In modern England it is reasonably possible to hope that the State is likely to behave fairly responsibly towards those who have to serve in a medical service. It is the agent not the master of its people, and the existing State services maintain high standards of professional integrity. At the same time, it is clearly essential, not merely that the "public relations" of the medical profession should be good, or that institutions like the "Radio Doctor" should exist, but that the doctor should have a clearly defined code of public duty and a critical approach to what is happening in society around him as it affects his own position. The whole question of what the position of the doctor in society is becomes an urgently practical one.

STANDING OF THE PROFESSION

Because this is so, it is worth realising the extent to which the high esteem, both social and professional, which doctors enjoy, is one of the distinctive products of modern times and not something which has always been inherent in the nature of things. There were small coteries of doctors of medicine and some outstanding surgeons gathered around the universities and the Court from the Middle Ages onward, but it was not until the 19th century that fully qualified doctors became easily available to the great majority of the population and that the social and financial status of the profession began to rise. In the old days, the medical man whom most ordinary people had contact with was the apothecary or the barber surgeon. The apothecary was a relatively humble person in society, exercising a useful and humdrum function. He was not in a position to assert great authority; nor had he the equipment to make striking advances in medical knowledge. His skill was very largely his own, his native shrewdness and deftness of hand being increased by experience rather than training, and his knowledge was acquired not primarily from learned books and technical journals but from his own developments and improvements by practice of a few simple and well-tried rules and remedies. His social status was certainly not among the gentry and was

Points of View

THE DOCTOR'S PROFESSION*

3. The Doctor, the State, and Society

WHAT is the general condition of the medical profession as it appears to the Christian man who is inquiring about his duty in relation to it? There is no doubt that in many of its aspects it reaches a high level of excellence and is regarded as doing so by Christian public opinion in general. It is common in these days to hear indignant moralists assert that they cannot understand how a man can be a good business man or a soldier and at the same time a Christian, but it is rarely that anyone says that it is impossible to be a doctor and to be a good Christian. Not only is the purpose which the medical profession is dedicated to serve, clearly an admirable one, but, on the whole, it is generally agreed that doctors achieve at least as high a degree of proficiency in their calling as any other professional group. Occasional criticisms are to be heard of the profession, whether from the lips of Mr. G. B. Shaw or from disgruntled frequenters of outpatient departments; but, where the criticism is responsible, it arises partly as a result of the high standards which the public has been taught by the profession itself to expect of the doctor.

These high standards are so frequently taken for granted that it is often not realised how extensive they are and what a considerable ethical achievement they represent in the world as we know it. Although he is no longer normally required to take the Hippocratic Oath, the doctor is bound to respect human life in all its forms; to preserve his patient's health, his secrets, and the honour of his family to the utmost of his power; to make discoveries revealed by his professional skill open to all; and to refrain from advertisement of his professional merits. There are other long-established obligations of the doctor that he still accepts which are less clearly defined but none the less binding, such as to relieve suffering to the utmost of his power at all times, to give at least a proportion of his services in charity and without reward, and to show complete and disinterested honesty in giving a professional opinion. It is significant of the strength of the doctor's code in an increasingly materialistic world that the discoverers of penicillin expected and received rewards for their labours which were very slight indeed compared with what they might have received if they had put their discovery to commercial uses. Apart from security restrictions during the war, no restraint was put upon the dissemination of information about the drug except what was necessary to prevent commercial interests from producing inferior imitations, and it was made available to the tramp as well as to the millionaire. What is more, the world would have been genuinely shocked if it had happened otherwise.

On the other hand, there are other aspects of the state of medicine today which prevent complacency. We have already noted the challenges which are being made today with great force to many of the most cherished traditions of the medical profession. Further, high though the profession's standards and achievements are, there are grave limitations of outlook and even professional competence imposed upon the doctor by the character of medical education. The distribution of doctors throughout the population in this country is still very uneven, and this is more spectacularly true in those less favoured parts of the world where we in this
country have special responsibilities, such as t

It would be a pity if a too ly technical conception of his vocation prevented ctor from giving due attention to these matters.

DOCTOR-CONFESSOR ?

other way in which the doctor's position in society his task today is the result of the operation of ifferent forces from those just mentioned. However the importance of indirect means of combating e may be, the day-to-day dealings of the doctor he patient remain, and certain aspects of life today give it a new significance. The doctor, as we have has great prestige in modern society, and he is led as the possessor of a mysterious and powerful g knowledge. If he possesses a sympathetic ıality and a ready willingness to listen to his ıt's accounts of his difficulties and distresses—a gness which is deliberately cultivated as part of technique by some doctors in ordinary practice as as by psychiatrists—then he is frequently in a on of embarrassing authority in relation to many patients. The situation is aggravated by the moral spiritual confusion of the present day. There are eople in modern society to whom ordinary men and n are able and willing to open up their deepest rns. The priest or minister used to perform this ion, either through the impersonal medium of the ssional or in that close intimacy of parson and e which was common when people lived most of lives in one place and where most of their leisure was spent in activities gathered round the church. now only a minority of people care much for the ions that priests and ministers exercise, and they r lack or do not seek the opportunity to avail them- s of their services. The power to give absolution sin, and direction for the spiritual life, is lightly ded by those who do not feel the need for forgiveness y to live the spiritual life. What such people do seek, however, is happiness here and now, and they are firmly convinced that good health is one of the roads to such happiness. Two considerations lead such people to the doctor and prompt them to seek from him more than strictly professional attention. A lingering sense that certain actions they wish to perform need to be justified, if not to God at least to themselves or to each other, leads people to the consulting-room to find a moral sanction. "Tell me doctor, is not my life with my wife ruining my health ?" "Can my nerves ever be right while my mother-in-law lives with us ?" "Can I possibly bear the financial and mental strain of another baby ?" Most doctors are only too familiar with such questions. The other consideration is that many people who fail to find happiness on their own resources come to the doctor looking for help and guidance which cannot be found on the medical level alone, but which they are prepared to accept from a doctor and not from a priest or a moralist, because the doctor has the reputation of being a realist, upon whose practical judgment they can rely.

What is the doctor to do in this situation ? It clearly raises great difficulties for him. He often finds himself willy-nilly dragged into complicated aspects of the personal lives of his patients, so that he is, for example, the only outside person who knows of some tragedy in the life of a family or of some impending rupture in its relationships, and finds himself compelled to exercise a pastoral office for which he is untrained and for the responsible exercise of which he certainly has not the time. It is no wonder that, in sheer self-defence and not on the basis of any preconceived theory, many doctors take the view described in our essay on The Doctor as Technician, and give the patients what they want, firmly ignoring any moral or spiritual implications in the situation with which they are confronted. Yet this is clearly an irresponsible attitude on the doctor's part. He may reasonably take the view with many patients that it is not his job to be a father-confessor, and that, in any case, he cannot take away from others the burden of the moral decisions they should properly bear. At the same time, he should not shrink from these opportunities of giving guidance and help to his fellows, with which the peculiar situation of his profession in these days presents him.

There have been cases in recent times of Communists who have gone into medicine because of the opportunities of influencing people in the interests of their ideology which medicine provides. Christianity is not an ideology in that sense, although Christians only too often use it as such. But the Christian doctor should use whatever opportunities come his way to help the wayward, confused, and lonely people of this age to a better understanding of themselves, and, where he can, to find the way to the place where they can recover full and responsible manhood once more. The burden of such demands is a heavy one: but we are members one of another, and when people make demands upon us, however inconvenient it may be, we cannot easily contract out of them.

"... There are eight possible occasions a day when people eat; early morning tea, breakfast, second breakfast, elevenses, lunch, afternoon tea, evening meal (whether in the form of high tea, dinner, or supper), bed-time snack. Of course, no-one gets through the whole eight of them, but this is the general pattern:

Wednesday	*Sunday*	
4%	4%	have early morning tea
93%	98%	have breakfast
3%	1%	have a second breakfast
23%	8%	have elevenses
99%	98%	have lunch
41%	42%	have afternoon tea
96%	96%	have a high tea, supper, or dinner
61%	46%	have a late evening snack."

Mass-Observation Bulletin, January, 1949, no. 24.

Peckham Health Centre is, of course, a research institution which tries to ascertain the criteria of health, and has only a light resemblance to the Health Centres proposed under the National Health Service, whose main function is curative.

lower than that of the clergy. The barber surgeon came a great deal lower down, for with him strong muscles and a non-squeamish stomach were the primary qualifications for opening an abscess or sawing a bone.

The modern medical profession has a very different *standing in society.* Even the humblest modern medical practitioner is recognised as belonging to a mysterious and impressive closed corporation, which has vested in it one of the most cherished forms of power in modern society—the power of knowledge, and knowledge of a kind eagerly sought after by all. Miracles were not expected from the apothecary. Popular imagination turned rather to the saint or to the witch or spellbinder for spectacular cures. Now, however, these expectations are largely transferred to the medical profession, and in many cases they appear to be fully justified. The popular press is constantly announcing the discovery of some new drug or the performance of some remarkable feat of surgery, and the atmosphere engendered, both by the press and by the numerous commercial organisations which carry out medical research, encourages the belief that sooner or later medical research will find the right cure for every disease that flesh is heir to.

It is true that, despite all this, an amazing amount of quackery still exists, together with distrust of the profession in some surprising quarters. One doctor remarks that he takes it for granted that his wealthier *patients are linked up with some form or another of* quackery. Lord Rutherford, the great physicist, regarded a butcher as his doctor and died of strangulated hernia. And whatever may be the ultimate reasons for the considerable popularity of Christian Science, particularly among a class which has had wide experience of dealings with doctors, one of the reasons must, at least, be a distrust of if not disillusionment with the medical profession. Nevertheless it remains broadly true that the medical profession as a whole, whatever people may think of particular doctors, is held in high esteem in modern society because it holds the key to what many people regard as among the most desirable possessions of life—freedom from pain and disease and the power to put off the pangs of death. Adverse comment may occasionally be heard about the fortunes earned by quacks out of credulous individuals, but doctors are able to earn a far better living than teachers or parsons without calling down upon their heads a quarter of the public criticism occasioned by a rise in the Burnham Scale or by the size of episcopal incomes. Of all types of modern scientific knowledge, that of the doctor is held in the highest esteem.

BRIGHTER SIDE OF SCIENCE

The reasons for this great advance in the position of the doctor are several. Medical knowledge is one large part of the great corpus of scientific knowledge which has developed so spectacularly in the last couple of centuries. It is a part which is more obviously and *directly related to our personal lives than any other.* The doctor is the best known in the widest circles of all professional men. The quality of his training has, on the whole, developed with the development of his knowledge. And, not least in importance, medical knowledge is one of the few parts of modern scientific knowledge which is almost entirely beneficial in effect. The aeroplane and the atom bomb are obviously highly *ambiguous human achievements, but few people* have serious doubts about the value of anæsthesia or penicillin.

This last point deserves a little further reflection. Would science itself stand as high in popular estimation as it does today if it were not possible to set the discovery of healing drugs over against that of poison gas, or the surgeon's scalpel against the devilish technical ingenuity of heavy armaments? Yet, there is a sense in which all
modern scientific knowledge is a unity. What
enables the doctor, in sharp contrast with o
tists, to appear as the kindly benefactor of
It is not anything necessarily inherent in the
method alone, which, as we are so constantly
may be used for good or ill. It is the fact
knowledge is in the hands of a profession whi
clearly defined standards of conduct from a g
tion which was already well established before

CHIEF FINANCIAL OFFICER

modern hospital with its rapidly growing and ated business problems needs the services of an experienced in finance and accounting, including accounts, cost accounts, business methods, and of internal financial control. The accounting ons made under the Act provide for such an n the person of the chief financial officer. He is arly the servant of the finance committee, m he should report direct. This is provided for egulations. At the same time he will realise that rices must necessarily be at the disposal of all tees and executive officers of the hospital as n requires them. It is to him that the hospital ties should look for information and guidance financial matters, and he is, or should be, the by which they carry out in detail their financial and system of control.

n this, it will be obvious that the appointment is ortant and responsible one. Not only must the be well versed in sound business principles, but st understand how to institute and maintain an t accounting system based on up-to-date methods; institute a system of internal financial control, ly as affecting cash and its equivalent in services aterials, but as affecting each and every transaction will ultimately result in the receipt or payment ; and how to prepare and operate a budget which t as an instrument of administrative control over finances of the hospital. He must understand ments and the investment of funds, and how to e intelligent periodical financial and statistical ents showing clearly and fully the financial position hospital. He is responsible for the keeping of all of account and financial and statistical records, amination of accounts, their presentation to the e committee, and payment of salaries and wages, and, t to the direction of the committee, he has sole of all finances of the hospital. He is not a book- —not a mere recording agent: he is a responsible and he should be clothed with the requisite ity.

chief financial officer should exercise his control distinct places in the system—in the spending ments, and in his own department. The heads spending departments should be made responsible n for carrying out duties related to the accounting s, such as the time-recording of all employees, ing stores received and issued, examination of es and accounts as to receipt of goods, and nation of goods for quantity and satisfactory r. Control, therefore, begins with the certification e records, and it is continued when the records reach uief financial officer for entry in the financial and sts accounts, and with the preparation and presenta- of specified periodical statements to the finance ittee. Thus the term "financial control" really unity of control as exercised by the chief ial officer under the direction of the finance ittee.

various executive officers are principally concerned the invention, enactment, and execution of their al, public, and social services, and the chief financial watches these services coldly and critically from oint of view of cost. He is a watch-dog, not a -hound; his financial organisation is not intended a drag on the wheel of progress, but to see that the al gets value for its money; that there is no ragance or avoidable waste; that the most mical methods are used: and generally, by sm and financial vigilance, to serve the same se as the profit and loss account in a commercial rn.

Disabilities

37. ANXIETY NEUROSIS—II

I HAVE a bad heredity, which includes alcoholism. Strong emotional disturbances and theatrically violent family rows in my childhood made, I am told, classic provision for later instability. But I was a useful citizen doing responsible work, physically and mentally on top of things, when, at the age of 30, I was knocked down by a car in the blackout. Without this accident I think I might have remained stable.

I had a head injury and I spent five weeks in hospital. London was not, perhaps, a good place at the time for a quiet convalescence. I went on overworking, as everyone did then, and felt more and more exhausted. I had nausea, giddiness, faintness, and tachycardia. Examination showed that the symptoms were functional. I went to a psychologist who prescribed rest and relaxation. I rested, failed to achieve relaxation, felt worse, and went back to work. A year later I was bombed out, and soon after that became unfit to go on with my job, though I was still getting the work done well and few people knew I was as ill as I was.

I could barely get myself to the office or stay in it until it was time to go. I was always exhausted, always cold; my hands were clammy with sweat; I cried weakly and easily. I was afraid to go to sleep; but I did sleep, to wake with a constricting headache, dizziness, and tachycardia. To these now familiar symptoms were added waves of panic fear followed by depression. The panics almost overwhelmed me. I felt very much more frightened when I was alone and but a little less frightened with other people. There were only three with whom I felt at all safe and able to relax, though even with them I was behind the screen of my fears. At the height of a panic I just wanted to run—anywhere. I usually made towards one of these reliable friends (two of them were doctors), from wherever I happened to be. I felt, however, that I must resist this running away, so I did not allow myself to reach safety unless I was in extremity. One of my devices to keep a hold on myself at this time was to avoid using my last chance, for I did not dare to think what would happen if it failed me. So I would merely go nearer to my bolt-hole and imagine the friendly welcome I should get. This would often quieten the panic enough for me to start out again, or at least not be a nuisance or use up any good will. Sometimes I was beaten and had to feel the acute shame and despair of asking for company. I felt the shame even when I hadn't to confess to my need.

One of the most distressing symptoms of this period, which was—and occasionally still is—associated with the panics, is a sensation of divided personality. There is Me 1 and there is Me 2, though neither of them is really me, for "I" am detached and merely the battleground for the two of them. Me 1 seems to be my intellect, with a good bedside manner, reassuring and commonsensical. Me 1 chivvies the wretched Me 2 along. Me 2 is the sickly panic-stricken me, who can reduce Me 1 to catch phrases, rote repetitions, and cursing. So far, Me 1 has remained on top even in the worst panics, and is helped by occupation. I have never fallen down on a job, and when I discovered that, as long as I felt reasonably safe, work helped, I kept my brain busy. I could not happily read modern psychological novels or books with much genuine emotional content. It was a bad day when I started Arthur Koestler's "Arrival and Departure" (I did not finish it); and "Crime and Punishment" was a mistake at the time too. History was good, learning some German was better. Tenses and declensions were magnificent repetitive stuff to cling to during panics, and to return to after the climax when

Reconstruction

RESPONSIBILITIES OF FINANCE COMMITTEES AND THEIR OFFICERS *

J. E. STONE
C.B.E., M.C., F.S.A.A.
DIRECTOR, DIVISION OF HOSPITAL FACILITIES, KING EDWARD'S HOSPITAL FUND FOR LONDON

REGULATIONS under the National Health Service Act require each board [illegible] to appoint a finance [illegible] ment committee a finance subcommittee. Though no direct provision is made for his appointment, the regulations state that "chief financial officer" means the treasurer or other officer charged with the duty of keeping the accounts of these bodies. The accounts he is required to keep are: (1) a balancing system of double-entry ledger accounts recording all the transactions of the board or committee on an income and expenditure basis; and (2) proper records relating to store accounts and stocktaking returns. He is also responsible to the board or committee for the proper collection of all moneys due and the proper payment of all debts, for the maintenance and completion of all financial records and returns required by the board or committee, or by the Minister, and for the submission of accounts to the auditor. He is not required by the regulations to hold a recognised accountancy or other professional qualification.

Finance lies at the root of all hospital administration, as indeed of most of our problems today, and the policy of every finance committee must be guided by the financial estimates approved by the board or committee. Acting for its board or committee, the finance committee is in effect a trustee for the funds entrusted to it, and acting in that capacity it has two important duties to perform: (1) to account strictly for all moneys entrusted to its charge; and (2) to secure that in the spending of such moneys the greatest economy consistent with efficiency is exercised.

DUTIES OF A FINANCE COMMITTEE

Such a committee is at once opposed to the erroneous but popular view that "the finance committee is only the committee which passes the bills." Rather is it the duty of the finance committee to consider and approve the estimates of expenditure; to inquire into and report upon both over-spendings and under-spendings (the latter are almost as important as the former); to exercise a continuous control over current expenditure; to consider periodical statements of expenditure and other financial returns; to examine from the financial point of view all proposals involving expenditure, whether of a revenue or capital nature; to supervise the methods of internal financial control; to examine all financial clauses in contracts; to consider the financial basis of all arrangements with other authorities for the treatment of patients; to supervise endowments under their control; and to review salaries and wages and submit recommendations thereon, and on matters of financial policy generally. The greater the efficiency of the control which can be exercised by this committee, the more effective will be the whole financial administration of the board or committee.

The key by which to test the efficiency, or laxity, of the administrative policy of a board or committee is generally to be found in standing orders. (These should be printed in booklet form and issued to members of boards, committees, and responsible officers, for they lose much
of their effectiveness when they are contained
of places—scattered in minute-books or
miscellaneous papers.) For the purposes of t
let us consider what these orders should
respect of finance committees. All the
in the list given below will not apply to a
committees, but it is comprehensive enough
the selection of items appropriate to any comm

SUGGESTED ORDERS

1. That the whole of the account-keeping of t
shall be centralised under the control of the chi
officer, who shall be directly responsible to t
committee.

2. That the chief financial officer shall institut
of internal audit and that he shall report to
committee from time to time as to whether the
being carried out in all departments of the hospital.

3. That all moneys received in the various d
of the hospital are regularly paid over to the chi
officer and that the system in force in each depart
be subject to examination by such officer.

4. That certain specified returns shall be pre
presented to the finance committee at stated tim
will include at least the following: (*a*) the budge
ment of estimated income and expenditure; (*b*)
statement comparing the actual with the estima
and expenditure, showing clearly all cases of ove
and under-spending and explanations of the o
cerned; (*c*) interim comparative statements of
expenditure; and (*d*) a summary of expenditure
costs, on a departmental basis.

5. That the finance committee shall allocate or
department or spending committee up to an am
approved estimates.

6. That no excess expenditure over sanction
without submission of a report as to the necessi
excess expenditure being made to the committee a
committee's approval by resolution has been obta

7. That a system of stores accounts be institu
view to securing effective control over all c
received, in custody, and issued for consumption.

8. That all work or articles the cost of which i
to exceed £*x* shall, unless purchased under a
contract already approved by the finance commit
subject of a resolution of such committee as th
for incurring such expenditure.

9. That purchases may not be made or wor
outside contract except on the authority of the
made after submission of requisitions from the var
ing committees or departments showing the goo
required and the estimated cost. Where such co
to exceed £*x* the goods shall, where practicable, be
or the work done by competition.

10. That orders for goods or work required to be
be prepared in the secretary's department, and
orders shall be on official forms.

11. That all accounts, duly certified by the he
appropriate spending departments, shall be delive
office of the chief financial officer at least . . . clear
the date of the meeting at which they are to be p
payment; and that all such accounts, salaries,
shall be subject to examination by the chief fina
before being submitted for approval.

12. That all contracts, tenders, &c., shall be op
first instance by the finance committee.

13. That no expenditure of a capital nature by
mittee or department of the hospital be incurred un
has been made to the finance committee on th
and as to the full estimated cost involved, inclu
tenance, and a resolution passed by the finance
approving such expenditure.

14. The chief financial officer shall report to t
committee any excess expenditure on contract
undertaken by own labour as soon as such
ascertained to have been incurred.

15. That all motions which may involve directly o
expenditure not otherwise provided for or increase
ture, or which would interfere with the financial p
hospital, shall stand referred to the finance com
consideration and report to the committee or b
any steps are taken.

ning Commentary by Peripatetic Correspondents

loch was shallow, but not so shallow that you ade it all. " Do ye wish a poat ? " asked Wullie. sh a poat and he went off to look for one, leaving ing from the shore. By the time he returned hree trout. " I have found a poat," he said, ie's no a very goot poat," he added cautiously. pected the poat. She was one of those flat-ed dinghy types with a pointed nose, intended y one person only. Gingerly we embarked and in the mackintoshes and fishing gear. Of course niel bitch elected to come too, so when we were e had about an inch of freeboard.

you swim, Wullie ? " I asked. " Not a stroke," ied, as though proud of the fact. We pushed at once began to take in water over the side om below. The bitch, resting her forepaws first gunwale aud then on the other, did not make diness ; each time she changed position we made a gallon. Our feet were soon awash, and the bag, floating around the blunt end, was playing polo with the mackintoshes. By this time we omewhere in the middle of the loch and could the bottom. " Better make for the shore," Each taking an oar we stood up and paddled. less uncomfortable than sitting up to the hips er.

nty yards from land we foundered. The bitch acefully in and swam ashore. Clutching my is rod I enjoined Wullie to hang on to something ruck out manfully. As I did so I noticed that was laughing fit to bust. " Hysterical, poor I thought—and bumped my knee on the bottom. been swimming for dear life in about three feet ter. Wullie, standing thigh-deep in the sunken continued to laugh. Everything was retrieved one crutch. We stripped and dried in the sun ind. Next day my tobacco was again smokable, ny matches strikable, and my watch—never very e—rather the better for the experience. " I *thocht* ass no a fery goot poat," said Wullie.

* * *

s morning one of my rare and prized private patients rged himself from hospital in a fury because n had refused to allow his small children to visit We discussed the matter amicably, and he gave me r, after which I went to give Matron a piece of ind. During the rather spirited interchange, in she defended the hospital rules—which also, ntally and barbarously, forbid parents to visit en—I became cloudily aware that some basic ple of the Universe was being unfolded. My ery that this was no less than the concept of Illness n coincided with, and was verified by, Matron's phant climactic remark about allowing children to very sick parents who were not expected to recover. see, we do temper Justice with Mercy." The l and scales became almost visible and I staggered the room.

an armchair after lunch I speculated further on the ct. The theme has of course been expounded by el Butler in *Erewhon*, where, you will recall, invalids sent to prison for their misdemeanour. Indeed, ever patients are nursed, particularly perhaps by nurses, this attitude is always latent and sometimes nes only too obvious when the nuisance is too much borne. Hence such behaviour in mental hospitals e saw in the *Snake Pit*. Unpleasant as this is, and as it must be deplored on civilised grounds, I do condemn it out of hand, for it is largely a natural lefence reaction.

e interesting fact is that my own small children the same viewpoint. Show them some victim of some luckless and legless individual, some cripple aralytic, and their immediate and uniform response Serve them right ! " After a longish period of failure vercome this callousness by reasoning I now realise t is at the bottom of it. Let us consider matters from child's angle. If it did not serve them right, if disease not suitable punishment for some crime, what possible principles of justice and order could reign in the Universe ? If suffering is without cause then there are no rules at all and anything may happen to anyone at any time. No, " Serves them right " is altogether safer and sounder than these shifting sands. The philosophical and religious questions concerned are not for the likes of me. I will merely adduce in additional evidence Camus's recent play *Caligula*, which has been rather misunderstood on this side of the Channel, for the portrayal of the emperor's vile and arbitrary cruelties seems to me to be based on the same human predicament. So unendurable does Caligula find the realisation of chance and meaningless suffering that he strives passionately to introduce at least some order and responsibility into the scheme of things by inflicting the punishments himself. One can sympathise with him.

Must we then conclude that crime and punishment, guilt and original sin, are concepts which, though not existing in the neutral Universe, are developed in self-defence in the minds of children ? Before accepting this it would be as well to remember that the little dears have incorporated all these charming notions in their superegos as the result of our parental admonitions and punishments. If they'd been brought up on proper lines we may assume that they would display much more of a savage or animal indifference to death and disease. At this point, appropriately enough, the thunderstorm woke me from my Saturday afternoon nap, as if to remind me of the advantages of having Olympian Jove as a public blame-taker.

* * *

In company with some other members of the Society of Applied Omphaloscopists (of whose scientific and social activities I have told you on previous occasions) I have been assisting at the meeting of our French colleagues, the Réunion Amicale des Frotteurs d'Arrières. It has been time and francs well spent. I heard complaint that a visitor heard nothing new, but years of association with the omphaloscopists has convinced me that a few hours of boredom on a hard seat—and French lecture-theatres are no more luxurious than our own—are the small affliction which wins the great prize of uninhibited gossip with our colleagues. The language difficulty was appalling to the point of absurdity, and it is small comfort that our neighbours are even worse linguists than ourselves. In the evening the president of the R.A.F.A. and his charming wife filled us with costly groceries and delicious intoxicants, and, to your correspondent at least, to cross the domestic threshold is the summum bonum of travel. At other times we sauntered freely and ate most expensively, the two occupations in Paris most suitable and rewarding to the elderly. How was the town ? The Americans are still in the Select, the Palais Chaillot is still the most comely of all modern buildings, the river still runs serenely under that arcade of lovely bridges. There are (of course) no new writers, no new painters ; but there are more forebrains working to capacity between Montmartre and the Lion of Belfort than anywhere in Europe. And I met a young man working with improvised apparatus in a dusty attic on a tweenymaid's salary ; if he lives we shall know something.

* * *

The following case-note was written by a Spanish refugee. I wish patients who write in their mother tongue were always as lucid.

> " On the 22nd Fibrery of 1945 Juan fold ill with high fiver. The Dr. during a month could not understand his illness and pronostiqued gastrigue, a month later geve the true pronostic, a pleurisie. So on 22.3.45 my wife cononduced him from M— to the clinica where he was opered at the same day of his arrival. From his body went out $1^1/_2$ litre of pus and had a pipe from in his back hole in order to let the liquid going out, but as he was allways in a high degree of fiver and the pus did not go quick enough on 21.4.45 the Drs decided to enlarger the back hole in accordance with the liquid remained still in the body. On 23.5.45 the Drs seeing that the previous operations have not been onough they made the last opperation at which they enlarged more the hole, whereby they did cut some pieces of bone. Then began the recovery of better and better state of health. A month later the back hole did close itself and two months after he was unknown by the Drs who were at his care, and now a day happily we think he is very healthy."

self-pity and despair threatened to take over. The day on which Me 1 and Me 2 first briefly coalesced brought a peace which perhaps only those who have been mentally ill can understand; though I expect a painless day to other Disabilities is an equally joyful experience.

I went to another psychologist. I was anxious to coöperate and I think I did. Some relief came simply from knowing that my sickness was not uncommon, that someone could at least understand what a panic could do, even if he could not altogether appreciate what it could be. It isn't always much help, if one is physically ill, to know that a lot of people are ill in the same way; but I found it most helpful to know that my neurosis was not an isolated or isolating thing. This is related, of course, to the fear of insanity; and the assurance that I was not likely to lose my wits acted like a supporting plaster, though I could not at once rely on it and still very occasionally mistrust it. This kind of psychotherapy—a sharing of the private burden—helped me to recover enough to know that work would restore some self-esteem. Though my mental capacity was never affected, my confidence was low and my energy limited. I took a whole-time responsible job, but I had to fight my symptoms every moment of the day. I was in despair. The psychologist suggested that I should take on a job in which he was professionally interested, in addition to the one I was doing. Then I knew I was neither dying nor insane. I believed I might recover, I almost believed that even disabled I was still a useful person. I took the job. That was one of the best bits of psychotherapy I have come across. A great fillip followed: a doctor friend told me "the natural tendency of a neurosis is to recover." This, I thought, sounded like experience and not mere encouragement. I did Coué with this phrase and it almost replaced German verbs.

For three years I had been unable to make a train journey alone. I now felt it was essential to my self-esteem to do so successfully. I arranged the journey carefully from one place of safety to another, had all my terrors beforehand, and travelled as if under light anæsthesia. I cannot say I lost my fears as a result, but I realised I could do what I had been unable to do.

Soon after this I had to learn to drive a car. I had always wanted to, but now I lacked confidence. I also knew what it was like to be a pedestrian casualty. My instructor was sarcastic and gloomy, but I passed the driving test without difficulty. Driving a car has been first-rate occupational therapy. That sounds irresponsible, but in fact the new responsibility widened my confidence, and fear developed into careful judgment. The vagaries of an old car ensured that the therapy was occupational. Waiting in traffic blocks brought at first a return of panics—and there was no running away.

My deepest terrors all this time were my own; but my behaviour at home, where I felt safe to take off my cumbersome armour, was distressing, and I know that only a saint can play successfully the rôle of neurotic's companion. That someone should play this part, however, is vital to the patient's comfort. A neurotic is disabled in the very part he must use to effect his recovery. Sometimes he is as good at it as at lifting himself by his own bootstraps, and he is lucky indeed if his home is a springboard of unalterable affection, encouragement, and good temper. Mine is; it remains resilient against despair, shame, and fear. I still do not find it easy to accept my neurosis as being no more my fault than a paralysed leg. Perhaps if I could wear a bandage round my head I should feel less ashamed. Perhaps if people did not say so freely "You're all right. You just want to pull yourself together" it would be better. It is, unfortunately, still necessary to try to hide one'

S.A. and will soon have it available for distribution ır side of the Atlantic.

studies upon consecutive unselected cases[3] have been criticised on the basis of lack of "controls." ere interested to notice that Professor Boyd could e a "considered opinion" when his group had asly not yet used controls. We believe this is an ıce of medical good sense, is in the most ancient ıumane tradition of our profession, and enables people to receive help much sooner than they wise would. Our patients have always been private ıts and we think there is a very obvious question dical honour involved in treating groups of private ıts as "controls." Controlled studies can be ating things. After an address one of us recently in Salt Lake City we were confronted by an rate controlled study proving that nitroglycerin for elief of angina had no value.

hope that the wide implications of the Boyd report e realised by the whole Manchester school.

MALLEOLAR FRACTURES

ı,—Mr. Herzog's article of July 9 might have oked my temper, normally excitable on the subject alleolar fractures, to a reply, had I not felt that annotation on the subject did much to correct his s and draw attention to the importance of the ıents around the ankle-joint in the mechanism of y. In particular, his diagram (figs. 3 and 4) showing possible shift of the fulcrum in adduction injuries rs from a failure to insert the collateral ligaments. fulcrum will obviously vary in position according hether the fibular collateral ligament remains intact ot. The pattern of malleolar fractures, so variable complex, is determined not only by the type of eolar strain to which the joint is subjected but by sequence in which the ligaments are ruptured, and the clinical value of familiarity with the radiographic arances is the facility with which the ligaments ured, and the mechanism, can be worked out. not only builds up in the mind a correct appreciation ıe soft-tissue damage, which, if the fractures involving articular surface are excluded, greatly outweighs n in importance, but also assists in the diagnosis igamentous injuries without fracture.

e suffer from a lack of agreement in the terminology l in relation to the ankle, in regard to results and to hanism. Thus tibial flexion, inversion, and adduction used synonymously by some authors, and with erent shades of meaning by others. We have not pted the easy French term "mixed oblique" for the nsy "first-degree external rotation fracture" of the la. Much unnecessary controversy has arisen from onfusion of meanings, and much from a failure to limit implications of the words used. The distinction ween the direct side-to-side movement of the talus, l the rotation around a horizontal anteroposterior s implied by abduction and adduction, is very essary, and I have used the words medial and lateral ft to imply this. It is certainly possible that if the le were supported externally this movement might ult in the bimalleolar fracture described, in which h malleoli were fractured transversely at the level the tibial *plafond*, but such a combination of events ould come under the head of direct violence during ich anything is possible, and our more interesting eculations are usually limited to indirect violence. a product of indirect injury, I have never seen the ion described, but a similar lesion may be produced by forced plantar flexion of the foot, though even then the fracture of the medial malleolus tends to be oblique in the lateral view. This explanation has weight of cadaver experiment to support it.

It is, however, with Mr. David Thomas (July 23) that I wish to cross swords. That the shade of Dupuytren should again cross the fields through which he strode of right of personality and opportunity rather than by scientific knowledge 150 years ago, proves how difficult it is to lay a ghost. On the strength of the patients' "stories" (my inverted commas) concerning 41 isolated fractures of the fibular malleolus of which 66% conformed to external rotation type of injury (the figure for a wider series is 70%) Mr. Thomas wishes to revive the theory that these are due to inversion strain. The sole fact adduced in support of this is the statement that "inversion strain is by common experience the most frequent indirect violence to which the ankle is subject." We cannot assume that this is therefore the most common form of violence producing fracture, but if we wish to draw such an analogy, we could take Thorndike[1] as an observer with whom most others are in agreement, who states that the commonest sprain of the ankle is a sprain of the anterior tibiofibular ligament, and deduce from this that the commonest form of fracture is likely to be due to external rotation or abduction, the only means by which this sprain can be produced.

Maisonneuve[2] had, I thought, settled this problem in 1840, though his conclusions were only very reluctantly accepted. As the result of a fortunate post-mortem examination on a fracture of the ankle, he showed that:

1. The fracture line was oblique from behind downwards and forwards.
2. That there was an accompanying rupture of the anterior fibres of the capsule and the *anterior fibres of the deltoid ligament.* (It was an external rotation fracture with displacement, and not the subperiosteal type.)
3. Only external rotation opened up the fracture line, and reproduced the deformity first seen.

This can be confirmed by anyone who examines a suitable case under anæsthesia with the assistance of radiography.

Are we also to neglect the numerous cadaver experiments, and the light they shed? Cadaver experiments are open to many errors, but on some points, such as the relation of the shape of the fracture line to the mechanical stresses employed, they are unanswerable. The largest series of experiments was made by Hönigschmied.[3] In 17 cases of adduction strain he produced 5 transverse fractures of the fibula at or about joint level and 12 cases of rupture of the fibular collateral ligament. By external rotation (22 cases) he produced 12 cases of the oblique or first-degree external rotation fracture, 8 cases of diastasis, and 2 of ruptured ligaments. Strangely enough, 5 of these were low oblique fractures, and 7 of them half oblique half transverse—i.e., the fracture line escaped anteriorly below the level of the tibial plafond in the first group, and took a transverse course from the centre of the fibula to the anterior margin of the fibula at the level of the tibial plafond in the second group. In the preradiographic era Hönigschmied was unaware of these finer clinical variants; and the fact that they are now encountered regularly, though in different proportions, in any series lends weight to his observations. I know of no experimenter who has produced this fracture by inversion.

Mechanical considerations based on the shape of the fracture line are also almost unanswerable. The shape of the majority of fractures is helical ("spiral" is the common though incorrect term) or shows a helical element. A helical fracture can only be produced by torsion, and I defy anyone to produce torsion of the fibula by inversion. Maisonneuve's analysis of the

Letters to the Editor

MECHANICAL RESPIRATION IN POLIOMYELITIS

SIR,—I have followed the contributions of Dr. Blackwell (July 16 and 30) and Dr. Ritchie Russell (July 23) with close interest, but feel that readers who encounter severe bulbar poliomyelitis for the first time may still be at a loss how to manage a case to the best advantage. Respiratory embarrassment, which may be of peripheral or central origin, or occasionally of both, is usually complicated by pharyngeal paralysis and troublesome accumulation of secretions, by a tendency to pulmonary collapse and pneumonia, and by cardiac failure of central origin. The cardiac failure may be accelerated by posture, which may aggravate œdema in the pons-medulla caused by the lesions inflicted by the virus—a condition somewhat similar in its effects to that found in late post-diphtheritic paralyses. Hence in bulbar cases frequent postural change, combined with intelligent use of the suction apparatus, is preferable to continuous tilting; it is safer when giving gastric feeds by nasal tube, and it is more comfortable to the patient. A recent case in a child of 13, characterised by alternating periods of coma and extreme motor restlessness, responded well to deliberate dehydration, intravenous administration of 50 ml. of 25% glucose four-hourly (6 injections), and systemic penicillin.

The Bragg-Paul apparatus, providing positive pressures, may prove better for such cases than the Drinker as a source of sustained mechanical respiration, while Eve's tilting or similar improvised stretcher will serve for short periods; a bronchoscopic table is rarely available for the purpose even in large hospitals. As regards the Oxford inflator, a serious defect is the absence of an easily controlled device for adjusting the degree of positive pressure applied to suit different ages and conditions. It should not be difficult to make a modification incorporating both this and automatic control such as is available on the McKesson apparatus. Perhaps the Ministry of Health might be induced to sponsor such an apparatus and a tilting bedstead with cot sides manually or mechanically operated, and so continue the tradition which the London County Council started 15 years ago when they secured a number of specially designed, stoutly constructed, Drinker-type machines which still give excellent service.

LIVER EXTRACTS IN PERNICIOUS ANÆMIA

SIR,—I have followed with interest the correspondence referring to the relative potency of British and American liver extracts, more especially because I have spent the past year in visiting various hæmatological clinics and laboratories in the United States; before that I saw very many patients with pernicious anæmia at the blood clinic at Edinburgh Royal Infirmary. I have seen nothing to suggest that there is any greater tendency for the patients in Edinburgh to relapse while under treatment with British extracts than for those at various clinics in the United States to relapse while under treatment with American extracts.

I should also like to add to the warnings given against any attempts to label liver extracts at present in terms of their vitamin-B_{12} content. It has been suggested by Stokstad et al.[1] that thioglycollic acid and other reducing agents, when added to the medium for the growth of *Lactobacillus leichmannii 313*, increase many times the growth response produced by vitamin B_{12}. My own experience and that of others in performing such assays suggests that there may be considerable variatio
response to the addition of such reducing agents,
depending on variations in technique, in orga
in other constituents of the medium; it may
the case that thioglycollic acid protects active
B_{12} against destruction during autoclaving of the
as has been suggested. Thus we have here a
in technique which may give a very marked
in the apparent content of active vitamin B_{12}.

Moreover, as has already been said in this
pondence, it has been shown that several fac
replace vitamin B_{12} in the growth of *L. lactis*
and *L. leichmannii*. Either these must be rem
paper chromatography, or the vitamin B_{12}
destroyed and a second estimation carried out.

Finally, although vitamin B_{12} is an extremely
hæmatopoietic substance that has been isolated
liver, it is by no means proven that vitamin B
pteroylglutamic acid are the only active factors i
extract prepared for oral administration or paren

Intensive investigations of these matters are
carried out at many centres and at present the only
assay method of liver extracts is the clinical on
batch being tested separately. When it is decide
a satisfactory assay method has been developed
labelling of liver extracts in terms of their vit
content, and if it is considered that such labelling
a true indication of anti-anæmic potency, it is
that exactly the same method of assay should be
used.

Meanwhile, if a doctor considers that the liver
which his patient is having is not potent it w
helpful if he would send a sample, or at least a
the brand and the batch number, to the clinic to
the patient is referred, or to the manufacturers co
so that further investigations may be carried out.

ere very painful. The face became suffused and the tivæ injected. About ten minutes later she complained ise itchiness of the skin, especially the face and scalp. ut of coughing lasted for about 1½ hours after which ped fairly suddenly. She then became fevered, the ature rising to 105°F by 4 P.M. An hour previously thematous blotchy rash had appeared, involving ally the whole of the body but most marked on the mbs. The rash began to fade after an hour and had tely disappeared on the following morning, by which ne felt quite well and the temperature was normal. her P.A.S. had been given, but at 4.30 P.M. on July 18 of 3 g. was again given. An almost exactly similar picture developed, but on this occasion the symptoms nced ten minutes after taking the drug. At 11.30 A.M. 19th a further dose of 3 g. produced a similar chain of commencing within two minutes of the drug being Further doses at 2 P.M. and 4.30 P.M. produced similar ns. A further 3 g. dose on July 26 produced the same me with the addition of vomiting, the reaction beginning iately after taking the P.A.S. A patch test using a olution of P.A.S. evoked no reaction and there was no ohilia.

attempt was then made to administer the drug under of 'Anthisan' 0·8 g. daily. On Aug. 23 0·25 g. P.A.S., n the 24th 0·5 g. was given without ill effect. A dose g. P.A.S. on the 25th however resulted in a similar on though in modified form. It was then decided mpt desensitisation, beginning with very small doses and sing the dose very slowly. Consequently on Sept. 16 was begun in dosage of 0·1 g. at three-hourly intervals mes daily. Every five days the dose was increased by Eventually by Jan. 28 the patient was taking 15 g. and this dosage was continued for eight weeks. No cts were observed at any time. That the desensitisation e permanent is shown by the fact that a further course g. daily was begun on June 14 without any toxic effects.

is interesting that the prominent symptoms of , skin irritation, and ceaseless violent unproductive ning which characterised the case reported by Hemming and Stewart were also observed in the now reported. In view of the increasing use of . it is important to know that desensitisation is ble should the necessity for it arise. Perhaps if r doses of the anti-histamine drugs had been given, could have been given in full dosage much more dly. Again, more rapid desensitisation might have achieved by increasing the dose more quickly in the stages. We were, however, unwilling to try to en desensitisation lest the unpleasant sensitisation tion recurred, thus forcing us to begin all over again ven to abandon the attempt.

NORMAN W. HORNE.

R,—I was interested in the report by Dr. J. N. Swanson y 23) on the occurrence of hypoprothrombinæmia ng treatment with p-aminosalicylic acid. In drawing ntion some time ago,[1] to the possibility of hypo- hrombinæmia, I suggested the simultaneous adminis- ion of vitamin K or its analogues for whatever ective effect they might have—especially to patients iving P.A.S. in high dosage over long periods or in m hæmorrhages such as hæmoptyses might be ected.

r. Swanson says that in several of his patients the od-prothrombin levels were determined by a method g viper venom as a source of thromboplastin. It been repeatedly shown,[2 3 4] however, that this test s not in fact measure the prothrombin content of plasma, and that the prothrombin percentages ulated from its results are considerably higher than true values obtained by using Quick's method of thrombin estimation. The dangers of accepting ures based upon the snake-venom test have also been previously stressed.[5 6] Probably the degree of hypoprothrombinæmia developing in Dr. Swanson's patients while under treatment with P.A.S. was much greater than actually reported—a fact which adds considerably to the importance of his observation that a potentially dangerous hyproprothrombinæmia can develop during administration of P.A.S.

JAMES A. O'CONNOR.

THE MEMBERSHIP

SIR,—All of us, particularly prospective candidates, will welcome the changes to be made in the membership examination as described in your issue of Aug. 6. But the committee have left at least one unresolved problem—that of a possible essay question—and have inserted a brief but familiar lament over the standard of English in the papers. That the standard is deplorable I have no doubt, but this is scarcely surprising considering the conditions under which the papers are written. The candidate is required to produce four well-balanced polished essays of moderate length in three hours, an exacting task even for a professional writer. Might I suggest that if the time for the examination were lengthened to, say, four hours, and that if a limit were placed on the number of words allowed per question (say 700), then the candidates would be able to turn out more "finished" replies, and the examiners might be able to broaden the scope of certain questions? The examiners would still retain the opportunity to test the candidates' mental agility in the vivas, and would save themselves time and trouble in the correction of the papers.

St. Thomas's Hospital, London, S.E.1.

H. E. M. KAY.

VASOMOTOR RHINORRHŒA TREATED WITH ANTHISAN

SIR,—In the paper you published last November[7] we reported that 19 of 35 cases of perennial vasomotor rhinorrhœa treated with 'Anthisan' derived complete symptomatic relief with reversion of the nasal mucosa to normal appearances. Six months after this initial course of treatment the patients were still all symptom-free without any further treatment.

Fifteen months after treatment we have followed up these 19 cases which were clinically and histologically cured. Of the 17 who reported (4 by letter), 14 were still symptom-free and 3 had return of symptoms. This means that of the 35 cases originally treated 14 (40%) had complete symptomatic relief for a period of fifteen months.

The 13 patients who attended were examined, and the findings were as follows:

No.	Condition during the past year	Appearance of nasal mucosa	Nasal secretion	Result of biopsy
1	well	slightly pale	dry	negative
2	well	normal	dry	negative
3	occasional upset	pale, allergic	mucoid	negative
4	well	normal	dry	negative
5	well	pale, allergic	mucoid	negative
6	well	slightly pale	dry	negative
7	well	normal	dry	negative
8	well	slightly pale	dry	negative
9	well	normal	dry	positive
10	occasional upset	pale, allergic	dry	borderline
11	well	normal	dry	borderline
12	well	normal	dry	borderline
13	well	normal	dry	borderline

It will be seen that though 11 were free from symptoms, in only 7 were nasal appearances completely normal, for in the other 6 the mucous membrane was somewhat pale and moist. In 5 cases nasal biopsy

forces developed between the malleoli can be proved mathematically, but is most readily demonstrated by his "two book" experiment. Place a ruler between two parallel books of equal weight and move it to either side. The book whose forward edge is pressed on by the ruler moves. Thus internal rotation-inversion or medial slide produces the vertical adduction fracture of the medial malleolus, a comparatively rare injury, and external rotation-abduction the external rotation fracture. Of the first-degree external rotation fracture there are three clinical variants, met with in my series of 126 cases in the following proportions:

1. Long sloping fibular fracture [illegible] between the anterior and posteric [illegible] to emerge anteriorly below the tibial plafond, and showing an unquestionable helical element (30 cases).
2. A shorter more oblique fracture, with a less marked helical element (81 cases).
3. A half oblique, half transverse fracture as described previously (15 cases).

These variations are most probably due to the variation in the element of abduction in the fracture, and the varying degree of descent of the anterior tibiofibular ligament on the malleolus.

If further evidence is needed, the additional fractures in the second-degree and third-degree cases frequently only allow of one explanation—external rotation under body-weight. Thus of Mr. Thomas's four groups of cases, group 1 are external rotation fractures, groups 2 and 3 adduction fractures, and group 4 due to external rotation in which the anterior tibiofibular ligament has yielded, permitting a partial diastasis, and corresponding to the "low Dupuytren fracture" of many observers.

I too have found that the mechanism of injury is often attributed by the patient to inversion—possibly because inversion starts the fall which leads to either external rotation of the foot on the fixed tibia or internal rotation of the tibia on the fixed foot. The injury occurs so quickly that few patients can describe it, and practically none enlarge upon it. If badgered they fall back on the simplest mechanism they understand. I hate undermining the confidence of a doctor in his patient in days when there has been so much talk of the loss of confidence of the patient in the doctor, but I would like Mr. Thomas to join me in being a complete sceptic with regard to the patient's story in these cases.

Northwood, Middlesex. J. G. BONNIN.

POLISHED FLOORS

SIR,—May I call attention to the peculiarly foolish practice one finds everywhere in hospitals and institutions for aged and infirm persons—namely, making floors slippery.

Hospital patients are not as a rule familiar with slippery floors; they do not have them in their own homes. In the day-time they manage fairly well; but in the night they get out of bed, entirely forgetting the danger, and often fall down, sustaining fractures, usually of the hips. Old people as a rule do not long survive this injury. It is, of course, uncertain whether this is the desired result; but everyone quite certainly knows it is of very frequent occurrence. It causes a lot of work and worry to the resident doctors, often called up in the night to render first-aid; and a good deal of extra work for the nurses and expense in materials used on these fracture cases, also X rays.

It seems that the sight of shining floors gives great satisfaction to medical superintendents, matrons, and members of committees. One of these said recently, "Oh! but unpolished linoleum looks so *dreadful*." This adjective might more truly be applied by the victim to the slippery floor.

VERITAS.

COMPLICATIONS OF PARA-AMINOSALI ACID THERAPY

SIR,—In their letter of July 23 (p. 174) Dr. E
and Dr. Stewart described some hitherto
complications of *p*-aminosalicylic acid (P.A.S.)
May we add a further side-effect from our own ex

Zarafonetis and others[1] observed a reducing s
in the urine of patients treated with *p*-amin
acid (P.A.B.) which could be identified as gluc
have observed a reducing substance in the ur
1–3 days of P.A.S. treatment which usually di
2–3 days after discontinuing the P.A.S. The
substance may still be detectable at a time w
urine no longer contains P.A.S. In two of o
the reducing substance was still present 10 and
after the end of P.A.S. therapy. In these two
reducing substance was identified as glucose.

According to published data,[2] [3] P.A.S. is not
in the form of glycuronate in man. Bray and
isolated a reducing substance from the urine of
receiving P.A.S., but no data have been publis
cerning the presence and nature of the reducing s
in human urine during P.A.S. treatment.

We have observed a reduction in rats' urine
administration of both P.A.S. and P.A.B. and al
aminobenzoic acid, but *p*-aminohippuric acid,
benzolsulphamide, and sodium oxybenzoate had n
effect. We showed,[5] with our colleagues Koltay,
and Majoros, that during excretion of the
substance kidney alkaline-phosphatase activ
significantly enhanced. The reducing substanc
rats' urine was not investigated in detail.

Further investigations were carried out in
the method of partition paper chromatography
recently in this journal.[6] In no further case
prove the presence of hexose or pentose, the
urines were strongly reducing. Even glycurona
not demonstrable.

On the basis of our experiments we suppose t
treatment sometimes gives rise to normoglycæm
suria. In the remaining cases some at present
metabolite seems to cause the reduction. A s
probably the same, is able to darken the urine,
not homogentisic acid. Further investigation
progress.

E. KEL
Szeged University, Hungary. D. HAL

SIR,—In your issue of July 23, Dr. Hemm
Dr. Stewart describe a case of acquired idio
to *p*-aminosalicylic acid (P.A.S.). This prompt
report a further case of drug sensitivity occurr
patient being treated with P.A.S., particul
desensitisation was successfully carried out, the
being enabled to tolerate a dosage of 15 g.
daily without toxic effect.

NORMAN W. HORNE.

—I was interested in the report by Dr. J. N. Swanson 23) on the occurrence of hypoprothrombinæmia treatment with *p*-aminosalicylic acid. In drawing on some time ago,[1] to the possibility of hypoombinæmia, I suggested the simultaneous adminis- of vitamin K or its analogues for whatever tive effect they might have—especially to patients ng P.A.S. in high dosage over long periods or in hæmorrhages such as hæmoptyses might be ed.

Swanson says that in several of his patients the prothrombin levels were determined by a method viper venom as a source of thromboplastin. It een repeatedly shown,[2] [3] [4] however, that this test ot in fact measure the prothrombin content of lasma, and that the prothrombin percentages ated from its results are considerably higher than ue values obtained by using Quick's method of ombin estimation. The dangers of accepting s based upon the snake-venom test have also been previously stressed.[5] [6] Probably the degree of hypoprothrombinæmia developing in Dr. Swanson's patients while under treatment with P.A.S. was much greater than actually reported—a fact which adds considerably to the importance of his observation that a potentially dangerous hypoprothrombinæmia can develop during administration of P.A.S.

Woodford Wells, Essex.

JAMES A. O'CONNOR.

THE MEMBERSHIP

SIR,—All of us, particularly prospective candidates, will welcome the changes to be made in the membership examination as described in your issue of Aug. 6. But the committee have left at least one unresolved problem—that of a possible essay question—and have inserted a brief but familiar lament over the standard of English in the papers. That the standard is deplorable I have no doubt, but this is scarcely surprising considering the conditions under which the papers are written. The candidate is required to produce four well-balanced polished essays of moderate length in three hours, an exacting task even for a professional writer. Might I suggest that if the time for the examination were lengthened to, say, four hours, and that if a limit were placed on the number of words allowed per question (say 700), then the candidates would be able to turn out more "finished" replies, and the examiners might be able to broaden the scope of certain questions? The examiners would still retain the opportunity to test the candidates' mental agility in the vivas, and would save themselves time and trouble in the correction of the papers.

St. Thomas's Hospital, London, S.E.1.

H. E. M. KAY.

VASOMOTOR RHINORRHŒA TREATED WITH ANTHISAN

SIR,—In the paper you published last November[7] we reported that 19 of 35 cases of perennial vasomotor rhinorrhœa treated with 'Anthisan' derived complete symptomatic relief with reversion of the nasal mucosa to normal appearances. Six months after this initial course of treatment the patients were still all symptom-free without any further treatment.

Fifteen months after treatment we have followed up these 19 cases which were clinically and histologically cured. Of the 17 who reported (4 by letter), 14 were still symptom-free and 3 had return of symptoms. This means that of the 35 cases originally treated 14 (40%) had complete symptomatic relief for a period of fifteen months.

The 13 patients who attended were examined, and the findings were as follows:

No.	Condition during the past year	Appearance of nasal mucosa	Nasal secretion	Result of biopsy
1	well	slightly pale	dry	negative
2	well	normal	dry	negative
3	occasional upset	pale, allergic	mucoid	negative
4	well	normal	dry	negative
5	well	pale, allergic	mucoid	negative
6	well	slightly pale	dry	negative
7	well	normal	dry	negative
8	well	slightly pale	dry	negative
9	well	normal	dry	positive
10	occasional upset	pale, allergic	dry	borderline
11	well	normal	dry	borderline
12	well	*normal*	dry	borderline
13	well	normal	dry	borderline

It will be seen that though 11 were free from symptoms, in only 7 were nasal appearances completely normal, for in the other 6 the mucous membrane was somewhat pale and moist. In 5 cases nasal biopsy

GUM-SALINE

SIR,—In connexion with Mr. Gibberd's letter of Feb. 26, I should like to mention that in 1937 Dr. H. Staub and I published a paper[1] on the action of colloidal carbohydrates on the circulating-plasma volume. Common starch, gum-arabic, and glycogen were assayed. Experiments made in dogs showed that glycogen (the preparations of Roche and Merck were used) in watery colloidal solution (20%), in doses of 0·25 g. per kg. given intravenously, raised the circulating plasma volume on the average by 21·7%. We believed that the colloidal nature of solutions containing glycogen would assure their retention in the blood-vessels. In another paper[2] I reported clinical observations on 4 cases treated with intravenous injections of 50–150 ml. of 20% glycogen dissolved in physiological salt solution; perfect tolerance was observed.

I suggest that more clinical trials should be made with glycogen solutions (20%). The solutions may be of value as a means of temporarily maintaining blood-volume. Glycogen is inexpensive, non-toxic, and possibly in addition supports the general detoxifying function of the liver.

SPONTANEOUS ALVEOLAR RUPTURE

SIR,—I read with great interest the two articles in your issue of May 28, on Spontaneous Pneumomediastinum in Pregnancy by Mr. D. J. MacRae and on Acute Mediastinal and Subcutaneous Emphysema by Dr. L. Fridjohn and Dr. P. G. Azzopardi. The impression left on the reader is that the authors of both papers regard Hamman[3] as the first to describe the ætiology and development of spontaneous interstitial emphysema in human pathology, although a few earlier writers are briefly quoted. May I therefore remark that I published four papers on this subject before Hamman, in the first of which, entitled the Symptomatology of Spontaneous Alveolar Rupture and its Consequences,[4] I thoroughly discussed the ætiology and symptoms observed in infants. I have never, however, claimed any priority in the description of the syndrome, for I knew that spontaneous alveolar rupture and its consequences were well known to Rokitansky,[5] the pioneer Viennese pathologist, as long ago as 1847. Roger, a French pædiatrician, observed and published cases of spontaneous rupture of the alveoli in 1862,[6] while Rauchfuss, the leading Russian pædiatrician of his time, described very well the ætiology and symptomatology of spontaneous alveolar rupture, in the first German handbook of pædiatrics in 1876–82.[7] In 1888 Friedrich Muller,[8] of Munich, gave a full account of the peculiar crunching sounds over the heart area. Dr. Fridjohn and Dr. Azzopardi say that "the first description of the peculiar crunching sound is credited to Muller (McGuire and Bean 1939) . . ." but add that "its full significance was recognised by Hamman (1937)."

My further contributions appeared in 1928 and In my last paper I mentioned that Guillot had two cases in early infancy in 1853–82.[12] My own tions, since I am a pædiatrician, dealt with rupture in infancy, and I observed that in born infants the function of the elastic fibres lungs may be impaired and the alveoli may rupture during attacks of cough. Alveolar newborn babies following artificial respiration not of course be considered spontaneous alveolar As to the heart, I described in infants weakness heart sounds due to interposition of air between and thoracic wall in the anterior mediastinum crunching sounds described by Müller could not

As the mechanism and ætiology of the so-call taneous alveolar rupture in infants and in identical or at least similar, I feel entitled to the above information.

POSTPARTUM PERITONITIS

SIR,—As a general practitioner I hesitantly following comments on the case of fulminating postpartum streptococcal peritonitis reported L. N. and M. H. Jackson in your issue of July 3

(1) A four-hourly record of the (mouth) tem would probably have shown pyrexia in the earlie of the illness. The pulse-rate was then only 80

(2) Abdominal rigidity is often absent or in puerperal peritonitis. The signs on the whole indefinite in the earlier stages.

(3) It seems unwise to rely solely on the sulp in puerperal infection. On the first suspicion of start penicillin therapy as well. Incidentally, good for the medical attendant's peace of min if subsequent events prove his fears to hav ill-founded.

Birmingham. W. M. CHE

SIR,—In the case reported by L. N. and M. H. the patient survived for $2^1/_2$ days after labour the temperature being raised on any of the occasions on which it was recorded.

From 1906 to 1936 the London Hospital isolation unit for severe cases of puerperal sep during the last ten years of its existence I majority of the cases admitted. During this p thirty years, which ended shortly before the intro of modern methods of chemotherapy, just ov cases were dealt with by this unit and the mortality was 25%. The absence of pyrexia w being encountered in a few cases of fulminati gangrene infection, and sometimes as a termina

EXPERIMENTS ON ANIMALS

—The letter signed by Major Humeand five others, r issue of Aug. 6, raises a problem which none of afford to ignore if we wish to retain the confidence steem of the public in respect of our reputed eness. My own views are fairly well known my colleagues and go far beyond those so rately set forth by Major Hume. Nevertheless s to me there is a great deal in what he says that surely appeal to quite a large number of doctors, am convinced that it would greatly redound to our in the eyes of the public if we expressed this in certain terms. Many, even among ourselves, are forget that when vivisectional research was intro- from the Continent into this country in the middle t century it was the medical profession itself, sed through the editorial columns of the *British al Journal*, and more especially of *The Lancet*, protested most loudly against the unnecessary es involved, and I would strongly recommend e interested in the history of the subject to look journals for the year 1863.

long has it been asseverated by protagonists of l experimentation that all animals are treated he same care and consideration as that given to ts in hospitals and nursing-homes. A large part antivivisection propaganda is concerned with ng this claim as mere moonshine, to give it no r description. There have been in recent years e number of experiments in this country which, ms to me, fall into the same category as those by Major Hume. I am prepared to give full ces if they are required by anyone. Briefly they be described as those involving the exposure of sthetised animals to blast and poison gases, and cotised animals to traumatic shock and the effects rns of every description (observation being con- l for long periods). Other types of experiment e the introduction of various substances into the us humour with consequent inflammation and ng of the eyeball. All these, from their very , are bound to be accompanied by severe suffering severe, who is to say? As G. W. Theobald wrote r issue of July 16 "pain is a subjective sensation can neither be measured nor defined."

l this brings me to the absurdity of the "pain attached to British vivisection licences, on which ny (including it would seem even Major Hume) to place reliance when defending vivisection as sed in this country from the charge of cruelty. s: "If any animal at any time is found to be ing severe pain which is likely to endure, such l shall forthwith be painlessly killed." I have no tion in asserting that this provision is absolutely meaningless. Who is to determine what severe pain is; if the animal is suffering from it, what constitutes a period "likely to endure"—how long is it, an hour, a day, a week; and who is to say if the pain is *likely* to endure or not? It is beyond question that the interest of the experiment, the bias of the experimenter, and enthusiasm in the case of one truly desirous of finding something which *might*, in his view, benefit humanity, would all be factors which would weigh heavily in the balance against the merciful treatment of the animal under experiment.

Dr. Golla expresses the opinion that the public realises that experiments in this country "are invariably conducted with humanity." Believe me, they are by no means convinced, though many scientific experimenters would like to believe it is so; and the more the public becomes acquainted with the contents of the scientific journals the less convinced they will become. The only way to offset this is for a large number of influential authorities in science and medicine to do as Major Hume and his co-signatories suggest and express their detestation of those types of experiment, whether abroad or in this country, which, as he says, are shocking to a normal human conscience.

Camberley. M. BEDDOW BAYLY.

MIGRAINE

SIR,—It may interest some of your readers to know that I have had some success in treating migraine with isopropylnoradrenaline ('Neo-epinine,' Burroughs Wellcome). It will abort attacks in many sufferers and seems to be a safe and convenient remedy. The patient should, of course, be completely at rest for ten minutes or so while the drug is being absorbed and acting. I do not suggest that this is an efficient form of therapy in the very severe bilious types of migraine, which require a much more thorough investigation and other methods of control, but I believe it to be a useful adjuvant. It has the great disadvantage of producing palpitations in most of these patients, which is alarming to them and may make them unwilling to use the drug, as is the case in three out of five who have reported no benefit from it. Against this, twelve patients with established migraine find that it brings them a good measure of relief and carry a supply about with them.

Birmingham and Midland Eye Hospital, Birmingham, 3.
K. M. HAY
Clinical Research Assistant.

THE DOCTOR'S PROFESSION

SIR,—Parts of the second essay in this series (Aug. 13) are, I think, dangerous to put before young students and doctors who will eventually have to make vital decisions in future practice.

1. Why is mankind in toto cut off from God and therefore corrupted by disease and mortality? Is this not rather a hopeless attitude with which to enter the world?

2. The article says: "'He made all things good' and man in His own image as the crowning glory of the Creation." To preserve this divine gift of life is the ultimate end of medicine; yet (says the writer) the parable of the Good Samaritan is misunderstood. By whom? Am I to understand that I must allow pain and suffering to persist to the end that life may be prolonged? I think that there can be no misunderstanding that the writer imagines a Christian God sharing out the pain and suffering allotted to the world, more to some unfortunate souls than to others. Rather carefully he skirts round the question of euthanasia by talking of pain-relieving drugs which might hasten an inevitable end by a few hours. I wonder what treatment he would give to an incurable and inoperable case of carcinoma of the rectum? Would he claim that this was part of the punishment of mankind cutting himself off from God?

3. With regard to suffering we again note that "the Christian knows . . . that suffering is ultimately due to sin." Yet, though we must not over-indulge and create a mental gloating in suffering, neither must we go to all lengths to alleviate that suffering by the methods of modern medicine. Did Christ, or for that matter any prophet, suggest that we should employ our knowledge of medicine in the modern sense of a "go-slow" method? How many of our patients, if we are *honest* doctors, really become drug-addicts in the strictest sense? How blessed is the infiltration and nerve block in cases of inoperable growth and morphine to those in the agony of weeping through intractable pain!

The Christian, we are told, lives in a "fallen world": I cannot honestly see the meaning of the statement. If I have a dental abscess or an acute appendix, is this the ultimate outcome of my being a unit of a "fallen world"? Must I therefore live in this state of pain unalleviated that I may not be numbered among the valetudinarian, the unhealthy product of an unhealthy society?

4. Finally, I would put this question to the writer: Does he consider the newly instituted National Health Service, providing indiscriminate care for all, rich and poor alike, as the outward expression of an unhealthy society?

Manchester. H. J. A. SIMMONS.

SIR,—Your venerable journal appears to me to be entering a phase which is not, I hope, indicative of senile decay. Some of your leading articles on the National Health Service might have been culled from the *New Statesman*, and now you favour us with outmoded evangelical articles on Christian ethics, more worthy of the *Church Times*. Now these admirable periodicals are readily available to those who wish to read them, but many subscribers to *The Lancet* must prefer that you would stick to your last and serve us with Medicine untinctured by either politics or religion.

Sherborne, Dorset. JOHN WHITTINGDALE.

THYROID SURGERY

SIR,—By way of supplement to the interesting records published by Dr. J. W. Linnell and Mr. J. E. Piercy (July 23), may I mention the following cases which caused some diagnostic difficulty:

(1) *"Goitre" as First Apparent Manifestation of Reticulosarcoma in a Girl of 18.*—A girl of 18 was operated on for what appeared to be a nodular goitre. The histological picture proved unusual: the thyroid gland was invaded and partly replaced by tumour-like tissue consisting of numerous atypical cells with large irregular nuclei. No definite diagnosis was given and malignancy was suggested. The girl was seen at intervals and for about two years appeared to be doing well. She was then readmitted with general malaise and weakness, and died shortly afterwards. Necropsy showed masses of enlarged lymph-gland in the mediastinum. The left lower lobe of the lungs was densely infiltrated by tumour-like tissue. There were nodular secondaries in the liver. The thyroid region showed only fibrous adhesions. Histological examination showed a reticulosarcoma.

(2) *Late Secondaries after Thyroidectomy.*—A middle-aged woman was admitted with severe pain in her back. The lumbar spine was surgically explored and was found surrounded by tumour-like tissue. Examination of a biopsy specimen showed well-differentiated thyroid tissue. She had had her thyroid removed five years before her present illness for "goitre." No histological report of the thyroid gland was available.

Tuberculosis of the thyroid gland is, I agree, extremely rare. On the other hand, chronic giant-cellular thyroiditis is not so rare. This shows giant-cell systems which have been described as "typical" tubercles, and tuberculosis of the thyroid gland has been mistakenly diagnosed.

I. FRIEDMANN.

RECURRENT MENINGITIS

SIR,—Dr. Norman's article of Aug. 13 reminc
a case of recurrent pneumococcal meningitis
observed over the last 3 years.

A woman, now aged 56, is suffering from ri
chronic otitis media, which heals for a time and
intervals.

Her first attack of meningitis started in Deceml
about 2 days after an attack of otitis media with
She spent several weeks in hospital and was
with sulphonamides and penicillin, making a
recovery.

The next attack was in April, 1948, following im
upon another attack of otitis media. She was tr
parenteral and intramuscular penicillin plus sulp
and again recovered completely, after only 3
hospital.

The third attack was in February, 1949. She w
pital 2 hours after onset, before the drum had p
and after combined penicillin and sulphadiazine
she left 2 weeks later fully convalescent.

In May, 1949, she had another attack of otitis
was sent immediately to hospital before definite
meningitis developed. A radical mastoidectomy
formed, but no gross ear disease was found. Radio
skull showed nothing abnormal.

The patient is now perfectly well.

Obituary

MAURICE NEWFIELD

M.R.C.S.

Newfield, who died on Aug. 13 at the age of 55,
man of talent and personality who, despite very
ealth, did valuable work for medicine and the
as author, journalist, and publisher. After service
first world war he qualified as L.M.S.S.A. from
g Cross Hospital in 1922 and took the Conjoint
ation the following year. He then held house-
tments at Charing Cross, and became a clinical
nt both there and at the Hospital for Sick Children.
any opportunities of active practice were closed
by ill health, and he turned more and more to
l journalism. One of his early ventures was the
medical section in the *Week End Book*, and on a
erious level he produced, in 1928, under the name
hael Fielding, a book entitled *Parenthood: Design*
ident, which long remained one of the most useful
its of birth-control. From 1928 to 1931 he was a
er of the staff of the *British Medical Journal*, after
he became publishing editor of the *British Encyclo-*
of Medical Practice and later managing editor of
h Hamilton Medical Books. He was also the editor
Eugenics Review.

. B. writes: "By his wide circle of friends, Maurice
eld will be remembered for many remarkable
ies. Most prominent among them, at least for me,
n indomitable courage in the face of a remorselessly
ping physical illness, and a shining vitality which
dily affliction could dim. His native vitality was
ive and wholly extraverted. It showed itself in a
lelight in his friends, about whom he loved to talk,
ring their peculiarities and expounding their idio-
asies with humorous appreciation. (He seemed to
out his friends as might a discriminating collector of
d'art, rejoicing in their rarity and their unique
s) It expressed itself in what was no less than a
mate interest in current affairs and events. It
flashes of imaginative wit and humour to his con-
ion, than which none was more entertaining; but
made him an unusually sensitive and attentive
er.

e had a penetrating intuition, a sort of sixth sense
ople; this, combined with unerring tact and with
usually shrewd judgment, made him a perfect
. He took an almost fierce pride in everything that
lited. His keen literary sense and the natural
of his thought made him an unsparing critic of
hoddy phrase, of the effort-saving cliché, of the
liced or muddled argument. Yet his kindliness and
nfailing courtesy enabled him to effect almost
al transformations in the material which passed
gh his hands and to incur nothing but gratitude
the many writers to whose paragraphs he gave
ice and finish. He was a man of perfect uprightness;
d, he was more than usually conscious of the ethical
ations of all actions, private no less than public.
ll never forget a short disquisition, arising paren-
ally from a quite different line of thought, about
thics of editing. He once told me—and I have
nt personal reasons for believing it to be entirely
—that, by the punctilious exercise of the editor's
gative throughout some three decades of editorial
he never lost a friend or had a quarrel.

here remains another quality which contributed to
vable character—an insuperable modesty. He
writing under pseudonyms. He did not in the least
his friends knowing about these pseudonyms; but
sliked publicity. Indeed, he shunned it much as
unned commiseration in his illness. With medical
gues he would sometimes discuss his symptoms:
e would talk of them with the same amused and
volent humour that he talked of his friends.
ver once heard him complain or say anything
aritable.

here can have been few literary personalities with
de a circle of affectionate and appreciative friends,
so concealed themselves from the reading public."

Newfield leaves a widow and a son.

ALBERT HOPKINSON

M.A., M.B. CAMB., B.SC. VICT.

Dr. Hopkinson, who died at his home in Cambridge on July 31, at the age of 85, was a blend of the Red and the White Rose; for his father, John Hopkinson, was a consulting engineer who became lord mayor of Manchester, while his mother was a Dewhurst of Skipton, Yorks. One of 13 children, he grew up in a tradition of family affection which his own children enjoyed in turn.

As a medical student at Emmanuel College, Cambridge, he took an active part in undergraduate life, gaining three college colours. Completing his clinical studies in Manchester at Owens College, he graduated M.B. Camb. in 1889, and after holding a house-appointment and the Bradley scholarship at Manchester Royal Infirmary he settled in practice at Withington, Manchester. Here he worked for many years and was greatly beloved; but after an operation in 1919 he decided to retire. Settled back in Cambridge he was appointed a demonstrator in anatomy in the dissecting-room, where the present regius professor of physic was one of his students. After half a lifetime in general practice it was natural that he should make a point of stressing the applications of anatomy in practice. Patient and painstaking, he took a keen personal interest in the undergraduates, many of whom kept in touch with him long after they had gone down. A colleague, who became his medical adviser, writes: "I can testify to the enormous regard and affection in which he was held by generations of Cambridge medical students between the wars. He was a handsome man, of extraordinary charm and simple modesty of manner. Devoutly religious and unswerving in his principles, he was full of kindly sympathy, and, like his friend, the late Sir Clifford Allbutt, representative of the most courtly tradition in the art of medicine."

As a young man Hopkinson was an all-round athlete, and all his life he was a keen mountaineer. For many years, with his four brothers, he was a member of the Alpine Club. When his climbing days were over, he took an especial interest in the Cambridge Mountaineering Club and a more active one in the University Swimming Club, swimming a mile when he was close on seventy. His family life was a very happy one, despite the loss of a son in the first world war, until the death of his wife ten years ago.

He is survived by two sons and two daughters. The civic tradition of the family has been carried on by his elder daughter, Lady (Lawrence) Bragg, who has lately held office as mayor of Cambridge; and one of his sons is a member of the medical profession.

Births, Marriages, and Deaths

BIRTHS

HERFORD.—On Aug. 6, the wife of Dr. M. E. M. Herford, D.S.O.—a daughter.

MURLEY.—On Aug. 12 at Radlett, the wife of Mr. R. S. Murley, M.S., F.R.C.S.—a son.

O'NEILL.—On Aug. 7, in London, the wife of Dr. Desmond O'Neill—a daughter.

PARKER.—On Aug. 5, at Gillingham, the wife of Colonel D. J. P. Parker, I.M.S. retd.—a daughter.

MARRIAGES

GODFREY—GREAVES.—On Aug. 8, at Chislehurst, John Charles Christopher Godfrey to Joan Frances Greaves, L.R.C.P.E.

STEWART—CLICK.—On Aug. 6, in London, Donald Norman Stewart, M.R.C.S., to Jean Muriel Click.

DEATHS

ASHBY.—On Aug. 6, in Leeds, Joe Edward Ashby, M.R.C.S., aged 59.

CRISP.—On Aug. 12, at Cheam, Thomas Crisp, M.D. Edin.

FOSTER.—On Aug. 5, at Danby, John Robert Foster, F.R.C.S.E., aged 81.

LAIDLAW.—On Aug. 9, at Cambridge, Janet Young Laidlaw, M.B. Lond., aged 66.

LEGGAT.—On Aug. 8, at Wellington, N.Z., Alexander Gordon Leggat, D.S.O., M.B. Glasg., D.P.H., of Newbury.

NEWFIELD.—On Aug. 13, at Gt. Bardfield, Maurice Newfield, M.R.C.S., aged 55.

WHITE.—On Aug. 4, in Guernsey, Digby Cooke White, M.D. Dubl., aged 81.

WHITELAW.—On Aug. 14, at Bathampton, Bath, James Charles Graham Whitelaw, M.A., M.B. Camb., aged 43.

WILLS.—On July 30, in Bath, James Tremlett Wills, M.B. Camb., aged 78.

Notes and News

MORE APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued the following supplementary list of approved names:

Approved names	*Other names*
Isoprenaline	Isopropylnoradrenaline. Aludrine. Neo-Epinine. Neo-adrenal. Neodrenal.
Menadoxime	Ammonium salt of 2-methyl-1 : 4-naphthaquinone-4-oxime *o*-carboxymethyl ether. Kapilon Soluble.
Mephenesin	1 : 2-dihydroxy-3-(2′-methylphenoxy) propane. Myanesin.
Mepyramine maleate	*N′*-*p*-methoxybenzyl-*N′*-dimethyl aminoethyl-2-aminopyridine hydrogen maleate. Anthisan.
Promethazine	*N*-(2′-dimethylamine-*n*-propyl) phenthiazine hydrochloride. Phenergan.
Phenadoxone	6-morpholino-4 : 4-diphenylheptan-3-one hydrochloride. Heptalgin.
Decamethonium iodide	Decamethylene-1 : 10-bistrimethylammonium di-iodide. C 10.
Hexamethonium iodide	Hexamethylene-1 : 6-bistrimethylammonium di-iodide. C 6.
Pentamethonium iodide	Pentamethylene-1 : 5-bistrimethylammonium di-iodide. C 5.

ADRENOCORTICOTROPHIC HORMONE IN ARTHRITIS

ACCORDING to British United Press, a "new hormone," developed from hog's pituitary glands by Messrs. Armour & Co., of Chicago, has had remarkably successful preliminary effects in arthritis, rheumatic fever, and gout. Dr. John Mote, medical director of the company, who is quoted as the source of this report, adds that supplies are limited. The hormone referred to is presumably an adrenocorticotrophic hormone (A.C.T.H.). As stated in our leading article of July 23, a hormone of this type, used at the Mayo Clinic, gave results comparable with those of 'Cortisone' (compound E), though the side-effects seemed to be more troublesome.

CHILDREN ON THE ROADS

AT a crossing in Western Avenue, Perivale, there have been 5 fatal accidents since 1947.[1] After a fatal accident there in March, the Ealing Town Council suggested to the Ministry of Transport that a footbridge two hundred yards away should be moved to this dangerous crossing; but no action followed, and a child of ten was killed there last week.

The toll of life taken at such danger spots can be considerable, and is of course exceeded by the number of non-fatal casualties. At a conference [2] arranged by the Pedestrians' Association in May, Subdivisional Inspector Anderson mentioned a junction in Southwark, where 8 children under fourteen had been injured in six months. The layout and traffic signals were inspected, Scotland Yard and the local police went into the facts, parents were interviewed—and in the following six months there was only one slight accident. Scotland Yard keeps a map to identify black spots, and measures are taken to reduce their dangers. A large part of the police force, he said, is immobilised daily seeing school-children across roads; and the police give talks and demonstrations at the schools. Nevertheless, 4500 people were killed and 150,000 injured on the roads last year; and four years of peace have brought 600,000 road casualties. It seems that it is not always easy to get safety devices set up. According to the *Quarterly News Letter* (July, 1949) of the association, when the Lambeth Road Safety Committee asked for a refuge at a point where several people had been injured, sanction was refused by the Ministry of Transport on grounds of economy; and a plan to install five new sets of traffic-lights at Stockport, to ease the traffic problem, has also been turned down.

Most speakers at the conference considered that the child under five is the responsibility of his mother; he should not be allowed out alone in the street, and the mother should be
more aware of him when she takes him out shoppi
suggested that old-fashioned reins for little childre
come back. In some parts of London "play str

RESEARCH IN OLD PEOPLE'S WELFA

FOR over a year a small group of people doing
in their local old people's welfare associations
London have been meeting to discuss points
interest. They have found many subjects whic
with closer study, and they are convinced that
group could profitably examine these issues and o
time will bring to light. They are therefore
those interested to join with them to form a Rese
(Old People's Welfare). The aims will be to cre
for the discussion of modern views on old peopl
to study special problems affecting the aged, t
a national programme of social reform based on
of these studies, and to provide information se
Ronald Gardner, the honorary secretary, will answ
sent to him at 195, Clarence Gate Gardens, Lond

A report on the work of the group indicates t
already being studied. They believe we must
old people to stay at work longer, learn new jobs, a
their output; but it would be cruel, they suggest,
old people to this programme under existing
Studies of the process of ageing might teach u
its rate and mitigate its effects, so that the el
maintain their health and work without physic
Meanwhile the group hope to establish an e
service to retrain the elderly for appropriate an
jobs. They note that many old people living al
kept fit if their minor ailments are treated earl
linking up old people's welfare organisations with l
of doctors they have ensured that the old peo
doctor early and are visited regularly after disc
hospital and during convalescence. They find
old people living on upper floors of houses or
may not receive their full coal ration, and may
of their rights or physically unable to attend th
to insist on them. They may also have nowhe
coal; and, since they often depend on it for cook
as warmth, deprivation is likely to affect their h
group have arranged an emergency distribution
which the local authorities take part, and have n
links between the fuel overseer and the O.P.W. or

They are also interested in the design, deco
equipment of old people's clubs, and are particula
that heating and lighting equipment should be
improve comfort and prevent accidents. Sev
subjects are under consideration, notably the p
care for the feet, proposals to provide a chea
service, and plans for better publicity about sup
pensions and for the aftercare of old people
from mental homes. They are clearly a keen
minded group, who will readily attract like spirits.

N.H.S. DISPENSING

were tested throughout England and Wales. Of
results of 748 were not known by June 30. Of the
; 1005 cases, no action was found necessary in
just over 90%. The other 96 cases—i.e., just under
re referred to the appropriate committee of the
council to consider whether there were any grounds
linary action against the chemist. It is still too
say in what proportion of cases such action will be
ipon, but under National Health Insurance a similar
as in force, and for the year 1932, for which results
ly available, out of 389 cases referred to the appro-
ommittee of the insurance committee, only 227
in disciplinary action. A considerable proportion
mples tested are drugs and dressings bought by the
ready-made and not compounded in his premises.
under the National Health Insurance Scheme, in
% of cases disciplinary action was found necessary;
ok the form either of a warning or of the with-
of part of the chemist's remuneration.

OPHTHALMOLOGISTS GO ABROAD

G the summer the Faculty of Ophthalmologists
ged visits to both Italy and Scandinavia.
y a party of 19, led by Mr. R. J. Buxton, travelled
, where Professor Bietti gave talks and demonstra-
d performed operations, including a keratoplasty
clocilodialysis (for the lowering of tension in certain
glaucoma). At Genoa they were shown round by
r Maggiore, seeing a number of new instruments and
experiments in colour-vision. In this and other
here seemed to be plenty of assistants and rooms
for such experiments. At Florence the clinic of
r Alajmo was visited, and the party watched a
of operations, including sclerectomy for glaucoma.
e Professor Cavara demonstrated the extracapsular
n for cataract, which he finds as satisfactory as the
sular and safer. Professor Leonardi in another hos-
monstrated cataract extraction by suction apparatus.
es Professor Lo Cascio performed nine cataract extrac-
45 minutes; he too had given up the intracapsular
for the extracapsular. He showed the operation
chment of the retina, using surface diathermy with
al needle-punctures. Finally at Bologna, in Professor
zio's clinic, papers were read on pituitary tumours
al infection in eye diseases.

g the Scandinavian tour, in June, under the leader-
Mr. W. Muirhead, a party of 20 was received by the
of the ophthalmic clinics at Copenhagen, Lund,
, Stockholm, Oslo, and Göteborg. Lectures, clinical
trations, and operative sessions were arranged, and the
were made welcome in the homes of their Scandinavian

TRAINING ASSISTANTS IN SCOTLAND

Department of Health for Scotland will shortly ask
medical practitioners who desire to undertake the
of assistants in their practices, and claim special
ts on this account, to apply for recognition as trainer-
oners. Recognition will be given by regional selection
tees appointed by the Secretary of State in consul-
vith the representative organisation of the profession.
itioner who has been recognised will himself engage
stant, and will claim a training grant from his local
ve council. The grant will comprise:

training fee for the practitioner himself at the rate of
ear;

coupment (up to a maximum of £700 per annum) of the
aid by the practitioner to the assistant; and

necessary, an allowance for a motor-car for the assistant.

ant will be payable only where a practitioner under-
he training in general medical practice of a recently
d doctor, and no increase in the number of patients
practitioner's list will be permissible on account of
gagement of the assistant. These arrangements do
ly to the employment of an assistant, whether experi-
r inexperienced, in a practice under ordinary conditions.
nt will be payable in such a case, and the practitioner
ed will not require to be recognised by the regional
n committee. Applications for recognition will be
o the regional medical officers of the Department of
for Scotland, at Edinburgh, Glasgow, Dundee, Aber-
nd Inverness, who will act as secretaries to the various
l selection committees.

DISTRIBUTION OF GENERAL PRACTITIONERS

THE following amendments have been made to the Medical Practices Committee's classification of executive-council areas described in our issue of July 30 (p. 211). Schedule 1 contains the names of parts where more doctors are needed; Schedule 4 of the "closed areas."

Schedule 1

ADDITIONS

Essex.—Barking, Chelmsford with Great Baddow, Chingford, Dagenham, Dovercourt and Harwich, Dunmow, Grays, Hornchurch with Harold Wood and Upminster, Laindon, Purfleet, Rainham, Rayleigh, Romford and Gidea Park, Seven Kings, Tilbury, Walthamstow, Wickford and Pitsea, Writtle.

DELETION

Soke of Peterborough.—Whittlesey and Market Deeping.

Schedule 4

ADDITIONS

Devon and Exeter.—Combe Martin.

Essex.—Earls Colne, Great Bentley, Hockley, Hatfield Broad Oak, Ingatestone and Stock, Roydon, Southminster, Thaxted, Tillingham, West Mersea.

Warwickshire.—Alcester R.D.

OPINIONS OF THE SERVICE

A SURVEY by Mass-Observation, the results of which are published in *News Review* (July 28), confirms the public's generally favourable attitude to the National Health Service. Three-quarters of the people questioned had made use of the service during its first year: 49% had used N.H.S. doctors, 42% dentists, and 17% oculists. Criticism was voiced mostly by the middle classes. Three-fifths of all those questioned who have had experience of the service feel that its introduction has benefited them; about a quarter say that it has hindered or inconvenienced them; while 1 in 6 reports that it makes no difference. People under 40 are more favourable than the more elderly. The commonest reason for praising the service, mentioned by 1 person in 3, is that it saves money. The major criticism is of the slowness and waiting now involved. "Although opinions on the wisdom of the Health Service differ considerably, there is almost complete unanimity that the attention given to patients has not suffered in any way. . . . Many still seem 'mildly surprised' by the excellence of the treatment." The doctor's attention to maternity cases and to children's ailments is usually the most highly praised. A small minority tell of ill-treatment or lack of interest. Very few, however, have found any difference in their relationship with their doctor. "Complaints of a deterioration in attitude are few, and where they occur, are usually accompanied, not by criticism of the Health Service, but by criticism of the doctor whose humanity is governed by his pocket." There is less unanimity about hospital treatment; but on the whole patients are satisfied.

Royal College of Obstetricians and Gynæcologists

The Queen has accepted the honorary fellowship of the college, of which she is the patron, and she will attend the college in the autumn to be formally admitted. Her Majesty has sent a donation of £1000 to the appeal which is being made by the college for funds to meet the financial demands of its ever-widening activities.

Faculty of Radiologists

The following officers have been appointed for 1949–50: president, Prof. B. W. Windeyer; vice-presidents, Dr. J. L. A. Grout and Dr. J. R. Nuttall; warden of the fellowship, Dr. S. Cochrane Shanks; editor, Dr. Peter Kerley; treasurer, Dr. J. W. McLaren; secretary, Dr. E. Rohan Williams.

Welsh National School of Medicine

Dr. W. F. Anderson has been appointed senior assistant in the medical unit of the Welsh National School of Medicine. Dr. Anderson is at present lecturer in materia medica and therapeutics in the University of Glasgow and assistant physician at Stobhill Hospital, Glasgow.

Institute of Neurology, London

Prof. J. Lawrence Pool will give a lecture on Topectomy; Cortical Ablation for Treatment of Mental Illness on Friday, Aug. 26 at 5 P.M. at the National Hospital, Queen Square (Institute of Neurology), W.C.1.

General Medical Council

An election of one member of the council to represent medical practitioners resident in England will be held in November.

Conference on Infertility

The Family Planning Association will hold their annual conference on this subject at Edinburgh on Sept. 17 and 18.

L'Union Internationale contre le Péril Vénérien

The 26th general assembly of this organisation is to be held in Rome from Sept. 12 to 16.

Industrial Nursing Service

The Royal College of Nursing is holding a conference on this subject at the college, Cavendish Square, London, W.1, on Oct. 7 and 8. Tickets may be had from the conference secretary.

Introduction to Social Psychiatry

The Social Psychotherapy Centre, London, is arranging a course of ten lectures on this subject to begin on Oct. 12. Further information will be found in our advertisement columns.

Association of Army Psychiatrists

The 7th reunion of Army psychiatrists will take place at Slater's Restaurant, 18, High Street Kensington, London, W.8, on Saturday, Sept. 24 at 7.30 P.M. Particulars may be had from Dr. J. C. Penton, the Old Farm House, 1, Gatehill Road, Northwood, Middlesex.

No. 2 General Hospital

The third reunion dinner of this hospital will be held on Saturday, Oct. 8, at 6.30 for 7.15 P.M. at Simpsons-in-the-Strand, with Colonel E. Scott in the chair. Tickets (14*s.*) may be had from Mr. A. E. Porritt, F.R.C.S., 10, Upper Wimpole Street, London, W.1.

Electronics Symposium, 1949

The Scientific Instrument Manufacturers Association hold their symposium this year at Examination Hall, Queen Square, London, W.C.1, from Nov. 2 to 4. There will also be an exhibition of British scientific and electronic instruments. Tickets may be had from the secretary of the association, 17, Princes Gate, S.W.7.

Paris Course on Renal Disease

An advanced course on medical disorders of the kidney is to be held at the Hôpital Broussais between Oct. 24 and 29, under the direction of Prof. Pasteur Vallery-Radot. Further information may be had from Dr. René Wolfromm, Clinique Médicale Propédeutique, Hôpital Broussais, 96, rue Didot, Paris 14e.

V.D. Study Group to visit U.S.A.

An international group of experts met in Washington on Aug. 15 to begin a three-month study of venereal diseases in the United States. They will present a report at the third session of the W.H.O. expert committee on venereal disease which meets in Washington from Oct. 10 to 20. Dr. Sidney Laird, venereologist for Ipswich, is a member of the group.

London Hospital

A postgraduate course will be held at the hospital from Oct. 26 to 29. Former students who wish to attend should write to Dr. A. E. Clark-Kennedy, the dean of the medical school, as soon as possible. The annual dinner will take place on Thursday, the 27th, at 7.45 P.M., at the Trocadero Restaurant, Piccadilly Circus, W.1, with Sir Eardley Holland in the chair. Tickets (21*s.*) may be had from Dr. R. R. Bomford, 6, Devonshire Place, W.1.

Liverpool Hospital Regional Board

On Aug. 4 the board was informed that the work of assessing the grading of senior medical and dental staff was almost concluded, and that probably by Oct. 1 all senior staff would have received their contracts. The board recorded its appreciation of the coöperation of consultants in connexion with the appointments to various hospital groups.

The senior administrative medical officer was authorised to investigate the possibility of obtaining additional temporary hospital accommodation for use during the winter months.

Empty Bottles

In conjunction with pharmacists the Ministry is launching an appeal to secure the return of medici used for N.H.S. prescriptions. It is estimated th way the public can help to save £800,000 a year o of the service. Hitherto the pharmacist has recei of 2½*d.* for each prescription, to cover the cost of the From Sept. 1 he will receive only 1¼*d.*

N.A.P.T. Colonial Awards

Scholarships offered by the National Associatio Prevention of Tuberculosis to enable colonial d study anti-tuberculosis methods in Great Britain awarded to Dr. R. K. Richardson (Trinidad) an A. W. E. Moreira, Dr. Abbas bin Haji Alias, and Din bin Ahmad (Federation of Malaya). A pri guineas for an essay by a medical officer in the se colonial government, on the Control of Tubercul British Colony, has been awarded to Dr. Vincent (Northern Nigeria).

Medical Auxiliary Workers

Mr. T. C. L. Nicole, of the Ministry of Health, has Mr. J. G. Paterson as *secretary of the eight commit* the chairmanship of Mr. V. Zachary Cope, F.R.C.S. set up by the Minister of Health and the Secretar for Scotland to review questions of recruitment, t qualifications of medical auxiliary workers in the Health Service. Vacancies on the committees have filled by the following appointments: *Laboratory Te* Prof. L. P. Garrod, F.R.C.P., and Dr. J. E. M *Almoner:* Prof. Clifford Wilson, M.D.

International Scientific Film Congress

The third International Scientific Film Congre held in Brussels from Sept. 30 to Oct. 5. In conjun the congress, there will be a scientific film festival, include four public sessions with films dealing with education, and scientific documentary. There will screening of medical films, when the audience will be to those with medical interests. The Scientific Fil tion of Great Britain is considering the films to be *as the British entry in the festival.* While the asso knowledge of most of the major films, it would information about privately produced films whi be suitable for inclusion. Full details should be s office of the association at 4, Great Russell Street W.C.1.

Second International Conference on Audiolog

Prof. Gunnar Holmgren (Sweden) presided conference which met in London on July 15 and 1 first day papers were read by Prof. Maurice Sourdill Dr. E. P. Fowler, jun. (U.S.A.), Prof. E. Luscher land), and Dr. Harvey Fletcher (U.S.A.). On the s Sir Wilson Jameson opened a symposium on the audiology carried out in England by the Ministry the Medical Research Council, and others. Other included Dr. C. S. Hallpike, Medical Research Dr. W. G. Radley, G.P.O. Research Station; Dadson, National Physical Laboratory; Dr. T. Department of Education of the Deaf, Manchester U Mr. Michael Reed, Ministry of Health; Dr. J. E. A. U Ministry of Education; Miss Edith Whetnall, Roya Throat, Nose, and Ear Hospital; Mr. R. Scott Metropolitan Ear, Nose, and Throat Hospital; Wilkins, the Social Survey; and Mr. Terence C Medical Research Council. In addition, there was stration of 'Medresco' hearing-aids and the Mi Health pattern pure tone audiometer. Dr. Eelco (Holland) is retiring from the secretaryship and is to be taken by Mr. Terence Cawthorne (England).

Appointments

, M.D., D.Sc., Ph.D. Edin., F.R.C.P.E., F.R.S.
SSOR OF PUBLIC HEALTH IN THE UNIVERSITY OF EDINBURGH

ou who have so recently been admitted to the owship of the profession of Medicine this must e the day of all days. It is highly improbable will ever encounter another that includes within span so great an abundance of that all-pervading iluted joy which comes only from the successful nent of the manifestly impossible.

ignificance of the ritual of this ceremony will not caped you. You will be aware of the dramatic rphosis that overtook you when the magic cap y touched your head. You now stand in relation ndergraduate that you were as does the infant unborn. The umbilical cord which formerly you to your alma mater has been cut and you ntered a larger world, to the conditions and tances of which you will be called upon, largely , to adjust yourself. The only bond which now you to your university is the emotional. Now ur undergraduate years are ended, you may begin to enjoy them.

THE TEACHER TESTED

have been vigorously tested and have been found . Now that your examinations are finished that teachers is about to begin. How we shall fare decided not by the extent and variety of our al knowledge and skill—vast as these are in certain es—nor yet by yours, but rather by the quality nward graces that you have cultivated and which present lie hidden beneath the gowns with which e draped, by the kind of culture and character you, whom we have taught, display when you eparted hence and have claimed your various n the open society which you will serve.

to be regretted that with these particular attributes s we are but little acquainted ; with their development e have unfortunately not been greatly concerned. ow so very little of you and you of us. There are easons for this. You are so many, we so few. f us are separated from you by a gulf that cannot ged ; for we belong to a generation that enjoyed, members, and clings to the world before the wars ife was gracious and hope unshackled. We are ly adjusted to the tortured world which we have thed to you and which is the only one known to you. are separated also because so many of you, ntly enchained by your ingrained respect for ity, have remained or have become semi-articulate company, your urgent thoughts being enmeshed inadequate vocabulary. Now that you have d from our dominion it is imperative that you at once begin to repair this grave deficiency. ossess the power of speech, the spring of man's ctual progress. But there is no profit in this sion unless it is transmitted into the ability to se. At all times you will require words, and the words in the right order, for conceptual thinking than for the expression of feeling.

have certainly offered you instruction without You are now qualified—qualified to depend for rofessional opinions and judgments upon the misreted findings of the laboratory report. You are ghly competent to blunt by misuse any instrument ecision that medical science may place in your . But as we bid you farewell and the best of good fortune, some of us find ourselves wondering whether or not we have done all that we could or should have done to advance your education. Have you, as the result of our intervention in your affairs, become or remained capable of critically observing, of skilfully experimenting, of discriminating between the true and the false ? Have we made you more capable than before of entertaining a new idea, a friend, and, especially, yourself ? Have we by our advocacy and example taught you to loathe intolerance, intellectual dishonesty, and inaccuracy ? Have we in our behaviour persuaded you to avoid malice, bitterness, and envy and to cultivate a constructive discontent concerning not only things in general but also, and especially, yourself ? Have we played a part in the fashioning of your secret ambition ? Have we taught you to seek, not wealth, not security, but the understanding heart ?

If not, then we must crave your pardon. Thus far your immaturity and upbringing and the circumstances of the academic *milieu* have impelled you to respect your teachers. Soon you will be in a position to judge us. We can but hope that in the future, if we have failed you, you may find it possible to forgive us.

This should not be impossible ; for the generation of your teachers has lived in a time of quite exceptional and violent change during which threatening peril corroded every one of the prized products of human achievement. We have been required to assume unusually heavy responsibilities in respect of the sifting and transmitting of ideas and ideals. In the confusion of dreadful war and in the conflict of uneasy peace some of us have failed to formulate any clear philosophy of life or to construct and adhere to any firm standard of values. In a world of flux and insecurity we have remained uncertain, and all too often we have avoided contemplation in busy activity.

It may well be that we in our distress have so instructed you that some of you are no longer capable of educating yourselves. If so, then indeed we have done great harm ; for the practice of medicine is the vocation of an educated person. The little that you know of technical matters will soon become obsolescent, and so unless your education proceeds nothing lies ahead of you save success —success as measured by yardsticks other than those in accord with the ideals of our profession. It is imperative therefore that your general education, so seriously retarded by the crowded content and the furious speed of the medical curriculum, shall now be resumed.

MEDICINE AND PEOPLE

To break a bottle on your bows in this way as you are launched into the sea of professional life is a matter of pleasant simplicity. But to provide you with the charts for your several voyages is indeed difficult, if not impossible, for you are to adventure into unknown waters. The place of Medicine in our society, the social function of Medicine, has latterly become so vastly changed that our experience is not a trustworthy guide.

The theory, content, aims, and function of Medicine in any age or place are reflections of the social theory and the social aims that prevail in that place at that time. Thus, for example, in its beginnings Medicine was a system of propitiative ritual exercised in intervention between puny frightened man and angry awful god. With the passing of time and the changing of man's conception of Nature and of himself, Medicine became one of the means whereby man sought to establish harmony between himself and his external physical world. Today and in this country, the interests of Medicine are becoming focused upon the disharmonies which exist between the biological nature of man on the one hand and, on the other, the social structures and institutions, the political and other creeds, and the economic systems which man has invented. Medicine is rapidly becoming a social science and as such is

---

oter's address to new medical graduates of the University Edinburgh on July 20, 1949.

regarded as one of the most potent instruments that a modern society can use in its enterprises in social engineering.

The major objective of Governments in this country in recent times has been and is the creation of the Welfare State. This phrase reveals in the clearest possible manner that the preservation and augmentation of the health, happiness, and efficiency of the people have become a prime preoccupation of good government. The inception of the National Health Service can only mean that Governments have been acting on the warrantable assumption that only by harnessing the willing and wholehearted loyalty of our profession to the ideas and ideals embodied in the project of a Welfare State can this objective be achieved. Medicine is now being employed as an instrument of social policy.

We are required to place at the disposal of the legislature our expert knowledge concerning the nature and variety of human needs in respect of health, happiness, and efficiency, and concerning also the ways in which these needs may be satisfied by adequate social and political action, in order that in increasing measure legislation may implement recommendations derived from and based upon medical knowledge. We, and especially you, are invited to be the architects of a new world fit for *Homo biologicus* to live in.

Very shortly you will become entangled in disputation concerning this health service as it now is. You will be invited to be offended by the peculiar behaviour of flamboyant personalities, seemingly intoxicated by the fumes of their own rhetoric. You will be encouraged to assess the value of this scheme by the extent of the financial disadvantages it confers upon you. If you are wise you will reserve judgment and give your attention to the ways in which this service, being improved, can provide the optimum conditions in which the practitioner of medicine can do the greatest good. Be critical of the exaggeration that is characteristic of the partisan. Be critical also of the unwillingness of older generations to endure that disturbance which change involves. The service is by no means perfect, far from it—the hopes and intentions of the visionary are always more magnificent than are the realities that emerge therefrom—but it is not a dismal failure. It is merely unfinished, and displays the deficiencies of the incomplete and still evolving. The important fact is that the general conception of a national health scheme claims the support of the majority of the people and of our profession. That this is so indicates that we as a people are far advanced in our social evolution. What is asked of you is that you should help repair the imperfections and deficiencies in the interests of the people as a whole, and in so doing assist in the evolutionary development of your chosen profession. The scheme will certainly fail unless, entering it, your spiritual equipment is at least the equal of your technical armamentarium.

RIGHTS, NEEDS, AND DANGERS

The intellectual atmosphere of this country is changing fast. Humanity is eagerly groping towards an ever-expanding dignity. Human rights and human needs are beginning to overtop all else in governmental considerations. A planned economy, careful of individual liberty, is taking shape.

It is for reasons such as these that so much of politics is medical knowledge applied to the affairs of a human population. No previous generation of medical graduates has ever been presented with such opportunities for high adventure, for full self-expression in dedicated service to mankind.

Ahead of you lurks danger—danger that derives from the very vastness of the machinery for the employment of Medicine, and danger that the intense specialisation within Medicine creates. Large-scale organisation is
in this age unavoidable; it has become
condition of human survival. But suc
organisation inevitably brings in its train t
overriding bureaucratic authority. Since
is so rife within Medicine it follows that for
of our opinions and judgments we have to
authoritative statements of others. You w

THE SEVEN SINS OF MEDI

Richard Asher
M.D. Lond., M.R.C.P.
PHYSICIAN, CENTRAL MIDDLESEX HOSPI

There is an unlimited number of medica
am going to catalogue and comment on se
in the hope that those students who wish to
may do so and those who wish to indulge i
enlarge their repertoire or refine their tech
seven sins are obscurity, cruelty, bad ma
specialisation, love of the rare, stupidity, a

OBSCURITY

Both in writing and in lecturing clear sty
words are best. Obscurity is bad, not only
difficult to understand but also because it
with profundity, just as a shallow muddy p
deep. Here is an example from a recent
writers wanted to say: "We judge men'
their working-places and their homes," but th
their meaning in this sentence: "It is genera
that the evaluation of the nutritional statu
munity should include assessments of the en
conditions under which individual membe
work." As Mr. Ivor Brown[1] has pointe
writing produces a slow weak ooze of words
keen forceful jet. The double negative is
way of making a simple statement harder to
and if we read "It is by no means far from
that the absence of tubercle bacilli is not
detected," few of us can say whether tubercl
present or not (nor do we care).

I warn students taking histories against
simple English of their patients into the jar
textbooks. If a patient says "if I go half-w
I feel I'm done for," these very words shoul

on March 17, 1948.

[1] Just Another Word. London, 1943.

es rather than "The patient complains that
ambulation up a moderate incline he suffers a
f impending dissolution."

CRUELTY

y is probably the most important and prevalent
the list I have chosen. Usually it is due to
lessness and not deliberate. *Mental cruelty* is
r and arises in three ways: (1) by saying too
(2) by saying too little; and (3) by the patient
rgotten. By saying too much we often burden
t with a load of anxiety which adds to the illness
trying to relieve. Many times I have seen
who felt well till they were told they had high
ressure or a heart murmur, and since that time
en afflicted with every grievous symptom which
e gathered from hearsay, from patent medicine
ements, and from "The Home Doctor." Before
patient anything of his illness it is essential to
whether it will help him or harm him, and with
practice one soon learns what it is wise to say.
aying too little one can cause the fear of the
n; the gaps may be filled in by the patient with
g inventions and superstitions. That is why
planation should be given to the patient who is
ed from hospital, both so that some of his
ess fears are removed and so that if he gets
he care of another doctor he can give a moderately
e account of what he has had. The doctor
know what fears and superstitions are common
patients so that he may allay them and prevent
cruelty. For example, a patient with shingles
rly always been told by his grandmother that
y meet in the middle you die," and the assurance
ither will they meet nor will he die may give
uch relief. Patients with mild arthritis are
terrified of becoming "crippled with rheu-
," and similarly many patients with bronchitis
uberculosis; in these cases reassurance is more
nt than medicine, and it is the doctor's duty to
these fears if possible.
y, forgetting the patient. I refer to that kind of
teaching and discussion where the patient is
as if he were unconscious, or discussed as if he
lay on the necropsy slab. It must be remem-
that patients have ears, and that sotto-voce
rings about polysyllabic diseases strike needless
nto their hearts.

l Cruelty

-investigation is a form of physical cruelty. If a
dying of secondary cancer and the primary cancer
n be discovered at necropsy, it is cruel to make
days uncomfortable by playing at "hunt the
" as one might play "hunt the slipper," and it
xtra work to the radiologists and pathologists.
s dying of heart-failure are happier without
catheters, arterial punctures, and other tests
of those who judge a patient with heart-failure
cardiac output in litres per minute rather than
number of stairs he can climb.
are some minor cruelties which can easily be
. Do not give mersalyl in the evening, so keeping
ient awake passing urine all night. Do not do a
al test-meal on a patient with pernicious anæmia
e is admitted with a hæmoglobin in the twenties;
s hæmoglobin up with liver treatment first—his
ydria will keep. Do not play at "pushing the
sonian"; there are enough signs of parkinsonism
nose a case without pushing him in the back to
w far he totters forward. Do not put sticking
on hairy limbs; you can easily shave them first.
t wheel elaborate trolleys to a patient's bedside
art sticking needles in him until you have given
word of reassurance and explanation.

BAD MANNERS

If students do not learn good manners while they are learning medicine they will be at a great disadvantage in dealing with patients, nurses, and colleagues.

Towards Patients.—I once asked a student to examine the abdomen of a patient lying in an outpatient cubicle. He dashed into the cubicle where she lay, flung back the blanket, plumped his hand on her abdomen, shouted "Gosh, what a beauty" (he was referring to the patient's enlarged spleen and not to her personal appearance), and dashed out again. Such behaviour must be condemned.

Other forms of bad manners are (1) impatience in taking a history from a slow-witted patient; (2) making jokes at the expense of the patient; and (3) reading the patient's newspaper which lies on his bed and displays headlines far more exciting than the story the patient is telling.

Towards Nurses,—Students will find that a courteous good morning to the sisters makes their access to patients and to ward equipment much easier. (In America the remark "Good morning, sister," is equivalent to saying "How goes it, honey?" and should be avoided.) Too many students or house-men call for a nurse in the manner of an impatient diner calling for a waiter.

Towards Medical Staff.—Years ago a student would take his hands out of his pockets even if a registrar passed him, and almost grovel at the sight of a chief. Perhaps the senior staff had too much majesty and pomp in those days, but the pendulum has swung in the other direction today. At any rate, I advise students not to examine an abdomen with one hand in the pocket, because it is an inefficient way of palpating; it will irritate physicians and give a bad impression in the examination hall. In general, students should aim at a reasonable respect for their seniors but avoid an oily deference. I further caution them against bad manners when they become more senior, and suggest such courtesies as asking their colleagues' permission before seeing a case in their wards, and writing and congratulating them on their publications or appointments.

OVER-SPECIALISATION

It is right that a doctor should have special interest and knowledge about one subject. It is wrong for him to show special indifference and ignorance about all other subjects. A good doctor should be a jack-of-all-trades and master of one. For example, a surgeon should be able to advise a patient with simple obesity about her diet and not refer her to an endocrine clinic; a gynæcologist should be capable of treating a mild iron-deficiency anæmia without referring her to an anæmia clinic; and a physician ought to squash a small ganglion on the back of the hand with his thumbs (or bible). I have known an eye surgeon after seeing a case of retinitis pigmentosa write in the notes: "This might be part of the Laurence-Moon-Biedl syndrome; is there any evidence of polydactyly?" For an ophthalmologist to feel himself incapable of counting fingers is surely the limit of over-specialisation; and, if nothing is done to stop this tendency, we shall have one physician who specialises in the first heart sound, and the other who is only concerned with the second.

Perhaps the worst feature of specialisation is that it makes doctors feel they are doing wrong to deal with even the simplest case if it lies within the protected area of somebody else's specialty. Particularly is this the case with psychiatry, which is regarded by other doctors with a mixture of suspicion, reverence, and ridicule. In Noel Coward's "Blithe Spirit" a character, referring to psychotherapy, says: "I refuse to go through months of expensive humiliation in order to find that at the age of ten I was desperately in love with my rocking-horse." A surgeon or a physician faced with a patient exhibiting some "functional" symptoms is likely to take a similar attitude, feeling that the origin of the simplest psychoneurotic symptoms lies buried in an uncharted swamp in which only the expert can poke with impunity—a swamp crawling with complexes and repressions, where nothing is what it seems and everything symbolises something indecent. This is a foolish attitude to take; a sensible physician or surgeon should be able to give wise counsel in the simpler case of neurosis.

Further, there is a complication of specialisation—that it allows bees to remain undisturbed within their masters' bonnets so that the allergist looks at the world through allergic-coloured glasses and beams myopically at a world where everything is allergic.

LOVE OF THE RARE (SPANOPHILIA)

This sin is more prevalent among students, because they lack the experience that teaches which illnesses are common and which are rare. It is responsible for the failure of bookworms to pass exams. Headache and vomiting are more often due to migraine than to cerebral tumour; nose-bleeding is more often due to picking the nose than to multiple hereditary hæmorrhagic telangiectasis; and wasting of the small muscles of the hand occurs in old age and rheumatoid arthritis more often than in motor-neurone disease or cervical rib.

COMMON STUPIDITY

By this I mean the opposite of common sense—common nonsense in fact. There are many kinds of this particular sin, but I think the commonest type is what might be called therapeutic automatism. No illness has a rigid code of treatment which must be advised in all circumstances; one must cut one's therapeutic coat according to the mental and economic cloth of one's patient. It is mere foolishness to order an elaborate diet for a busy working-class woman with instructions to add on the fourth day $1^3/_4$ oz. of steamed red mullet to the graduated scheme prescribed. I saw the finest example of therapeutic automatism as a medical student when I was skating one winter on the local squire's pond, watching all the quality displaying their skill. A woman fell and broke her tibia. I longed to treat her, but I was only a student. "She mustn't be moved till the doctor comes; we must treat her for shock," cried all the bystanders. From within the squire's house maids hurried out with hot-water bottles, while sympathetic ladies lent their furs. Musquash was piled upon sealskin, and nutria lay upon mink. The stricken woman groaned beneath this furry mound. "The treatment of shock is always warmth" repeated the ladies (who had taken their red-cross course), but I had learned physics during my 1st M.B. and felt that another factor was at work: "Warmth may be good for shock," I thought, "but it also melts ice." It was only at the last moment that these zealous first-aiders were persuaded to abandon their treatment and drag the lady off the ice; otherwise the patient, together with a valuable collection of furs, might have been lost. I mention this to show that patients should never be treated by rote and rule, for there may be special circumstances.

SLOTH

Medical sloth can be physical or mental. Physical sloth exists more than we like to admit. When blood-banks and standard apparatus made transfusion quick and easy, the number of transfusions quadrupled in a few years, which makes it regrettably apparent that the easiness of treatment rather than its urgency may decide whether or not it is given.

Physical Sloth

This often causes the omission of blood-pressure estimations, ophthalmoscopy, or rectal examination, and leads to lapses in aseptic ritual (if a lumbar-puncture needle touches the bed-clothes, it is tempting to pretend not to notice it). Physical sloth may also overworked nurse who, tired of counting adds one more twenty to the row of twenties the chart, and this may stretch the doctor's belief greatly.

Mental Sloth

This is commoner and more important. E history-taking is sloth the great danger. If hot, the patient deaf, the doctor in a hurr history garnished with reminiscences and irre requires enormous patience and concentratio the essence from it. One form of unconscio worth special mention. Do not accept th diagnosis when taking a history—find out his Rheumatic fever at the age of 10 years is imp the patient's statement that he had it needs am He may have been one day in bed with a p ankle which his aunt said was rheumatic feve other hand, may have been twelve weeks i flitting joint pains of great severity starting a throat. Similarly with diet (so important a history in cases of anæmia), do not write " or "fair," but find out what exactly your p at each meal, and you will be astonished women are living on bread and margarine an cups of tea.

Lastly, beware of sloth in thinking. If y lazy to think for yourselves, you will fall an e the less thoughtful papers and publicatio accepting the myth and mumpsimus against Forbes[2] has so ably warned us. If you healthy doubt (without being unduly sceptica have the experience of the Queen of the *Iolanthe*:

"On fire that glows
With heat intense
I turn the hose
Of common sense
And out it goes
At small expense."

Please adopt this attitude with everything I and realise that much of it may be nonsense

---

CONTRIBUTION OF THE EMPLO HISTORY TO CLINICAL DIAGN

A. MEIKLEJOHN
M.D. Glasg., D.P.H.
SOMETIME MEMBER OF THE MEDICAL BOARD FOR
AND ASBESTOSIS

> "'When you come to a patient's house, yo him what sort of pains he has, what caused many days he has been ill, whether the bowels and what sort of food he eats.' So says Hippo work *Affections*. I may venture to add one tion: what occupation does he follow?"—
> RAMAZZINI (1700) (trans. W. C. Wright, 1940).

The influence of occupation on health, someti ing in specific diseases of tradesmen, is established and recognised in our common such expressions as painters' colic, potters' r lung, boilermakers' deafness, hatters' sh weavers' cough. Accordingly, the occupatio (or, better, the employment history) is of c importance in clinical practice. But of a wo not sufficient to inquire "what occupatio follow," for, as observed by Bramwell and K "to take an adequate history is far more diffic make an adequate physical examination . . . . considerable clinical experience to elicit and t its true value all the evidence which can b from interrogating the patient."

---

[2] Forbes, J. R. *Lancet*, 1946, ii, 293.

azzini's suggestion, shrewd as it is, marks only a advance, because it fails to emphasise that the from which a workman may suffer does not arily reflect his present occupation, but rather previous occupation or indeed bad conditions or formerly prevailing in the same employment e 1935). So the recording of the occupational y involves a definite technique which should be ed at the first consultation and should not (as so happens) await the direction of evidence subse- y revealed by radiographic, biochemical, blood, tum examination. The history should commence age of leaving school and should itemise the periods ature of employments in chronological order to Each separate employment—and in particular even this may have to be subdivided into periods uld be amplified by reference to the raw materials, ols, the processes, the general environmental con- s, and any protective devices in use. Hours of shifts, meal-hours, wages, and the occurrence of r illness in fellow workmen—all are important. ntally workmen engaged in certain specific risks on their person some intimation of the risk; a ice which might usefully be extended to certain ndustrial diseases. Examples are:

he Worker's Register in Silicosis and Asbestosis.

Form 1893, Ministry of Labour and National Service, to workmen exposed to anthrax infection.

Identity discs worn round neck or wrist by caisson rs.

eason of critical episodes this practice might prove l in cases of diabetes, epilepsy, and renal insufficiency. the overwhelming majority of cases the employ- history will provide no substantial contribution to liagnosis; but it will never fail to assist in the ment and management of the patient, as implied in n to work, rehabilitation, and resettlement. The pline of the practice is invaluable, equalled only by ast phase—attendance at the necropsy. The time culcate and develop the technique is during the e period of clinical instruction in the wards and out- nt departments, and there are few surer and quicker s of gaining a patient's confidence than the display telligent knowledge of his job.

do not propose to elaborate this theme, but rather llustrate it by reference to some interesting fatal s of silicosis.

SILICOSIS IN GRAVEDIGGERS

certain parts of England—Cheshire—and Derbyshire es were and still are prepared in solid sandstone . The excavation is achieved by workmen using umatic hammers and drills; in the narrow cell, icularly in dry weather, the intensity of the dust d is very high and even the use of water does little ontrol it.

hree workmen, employed at a cemetery near Birken- d for 23, 26, and 27 years, died of massive silicosis, ch in two cases was complicated by tuberculosis. eral other cases were diagnosed in life. While these kmen were classified as gravediggers, they were in drillers in silica rock.

TUNNELLERS

uring the war deep shelters were excavated in the crops of sandstone near Birkenhead. The drilling undertaken by casual labourers with no previous osure to a silica risk. Three cases were observed in ich death occurred from massive silicosis, one com- ated by tuberculosis, after $1^{1}/_{2}$–3 years' work. In ry instance the disease did not become apparent ring the course of the employment, but appeared only ile the workman was unemployed or engaged in some harmless labouring. The occupation in each case was recorded as general labourer. Similar cases have occurred, and others may yet appear, among labourers employed in excavating underground petrol reservoirs and ammunition dumps.

SOAP-PACKERS

Scouring powders composed of fine siliceous sand mixed with washing-soda or soap-powder are in daily use for household cleaning. As a rule these are prepared and packed mechanically in modern factories, but occasionally, in the neighbourhood of natural deposits of suitable sand, the work is carried out by hand in tumble-down sheds. Three women aged 18, 24, and 38 years, after 2–5 years' work died of silicosis accompanied by tuberculosis. During life these cases were treated as simple tuberculosis, and only when death occurred was attention focused on the nature of the materials which they had been packing.

BRICKLAYERS

This occupation is usually associated with housing, but many bricklayers are regularly employed in coal-mines, foundries, and potteries. In the last two they are engaged not only in building but in the demolition, repair, and rebuilding of furnace and oven linings. This involves the cutting and fixing of special refractory bricks, 80% silica, in closely confined spaces where dust control is practically impossible and protective helmets and masks intolerable. The silicosis risk is of a very high order, particularly during demolition of old refractory linings. Our necropsy records contain two cases of advanced silicosis, from this cause but several more were identified clinically.

PREPARATION OF COLOURS AND GLAZES

To the industrial toxicologist the work of the colour grinder and mixer and leadhouse worker might suggest poisoning by arsenic, chrome, mercury, lead, or some rare metal; but the possibility of silicosis might easily escape notice if careful investigation were not made into the ingredients and processes. In the preparation of ceramic colours and low-solubility lead glazes (fritted lead; lead silicate), powdered silica is an important constituent, and the workman is exposed to the inhalation of the siliceous dust during mixing and grinding. Moreover, before the introduction of mechanical handling, the work was often carried out under very unsatisfactory conditions. Seven cases of death from silicosis or silicosis accompanied by tuberculosis appear in this series. It may be argued that investigation of the pulmonary disease would have included an X-ray film, whereby the condition would have been recognised. This is only partially true, for in one case sudden death followed coronary-artery occlusion while two others died of acute pneumonia and one was treated as simple tuberculosis.

SAGGAR-MAKERS

Saggars are fireclay boxes in which pottery is "placed" for biscuit firing. The handling and manipulation of fireclay is not considered to involve the risk of silicosis, though this does not preclude the possibility of other forms of pneumoconiosis. Quantities of grog, however, such as broken saggars (crusted with placing sand or flint) or ground earthenware pitchers, are frequently added to the fireclay, thereby exposing the workmen to the inhalation of free silica. In eight necropsies among saggar-makers evidence of silicosis was noted. Over a period of 15 years this may appear insignificant, but it should be remembered that the number of such workmen at risk is very small.

Other unusual cases of silicosis were observed in connexion with crushing poultry grit in which sandstone was added to the limestone, grinding of fireclay slabs on an emery disc grinder, among sanitary fireclay setters who used powdered flint as a parting powder, and among potters' dippers and glost placers. The details of these, however, need not be presented, for enough has been said to suggest the importance of a comprehensive employment history. No doctor can be expected to be familiar with the details of all industries, but every opportunity should be taken to study those within the area of his practice. That is only possible by visits to the factories, mines, and other places of employment.

SUMMARY

The employment history is invaluable and indeed indispensable in clinical practice. It is not sufficient to name the workman's occupation; the recording involves a precise technique which should be impressed on the student throughout his clinical studies.

A number of unusual cases of silicosis in gravediggers, tunnellers, soap-packers, bricklayers, colour mixers and grinders, leadhouse workers, and saggar-makers, is presented by way of illustration.

My thanks are due to Dr. Charles L. Sutherland and the members of the Medical Board for Silicosis and Asbestosis, 1931–46.

FUNCTION OF THE M.D. DEGREE

RAYMOND WHITEHEAD
M.D., D.Sc. Manc.
READER IN PATHOLOGY, UNIVERSITY OF MANCHESTER

A BACHELOR of medicine of a British university may proceed to the higher degree of doctor of medicine by examination alone, by examination and thesis, or by thesis alone. The candidate is seldom free to choose which of these methods he will adopt; most universities prescribe a single method, usually examination and thesis or thesis only. In recent years there has been considerable criticism of the arrangements for the M.D.; the critics include both examiners and candidates, and between them they represent many universities. Some think that the M.D. by examination duplicates other higher qualifications, such as the M.R.C.P. and D.P.H., and that the M.D. should be obtainable only by thesis; others condemn the M.D. by examination and thesis because it entails a division of energy between study and research; objections have been made to the narrow interpretation of medicine that excludes surgical topics as subjects for theses; the appropriateness of awarding gold medals and other distinctions with the degree has been questioned. These criticisms suggest that the M.D. is imperfectly adapted to current needs and deserve careful study.

REQUIREMENTS FOR THE M.D.

Table I shows that the requirements for the M.D. vary widely from one university to another.

Though London prescribes examination as the normal avenue to the degree, the regulations permit a thesis, which may exempt the candidate from part of the examination, or, in the special case of pathology, from the whole of it. Of the 4 universities requiring the candidate to proceed by thesis, 3 make further stipulations: Cambridge may allow or require an examination, Dublin requires an oral examination on the thesis and on general medicine, and Manchester may require an oral examination on the thesis only. Of the 8 universities requiring examination and thesis, all except Wales may waive the examination. Ireland requires published work if examination *does not form* part of the procedure.

When a thesis forms part or the whole of tl ment, previous approval of the subject is required, and exclusively surgical topics are prohibited; Edinburgh, St. Andrews, and I implication prohibit theses in chemistry, physic and zoology. The range of permitted topics is widest at Manchester, the requirement bein "on some subject coming within the scoj Faculty of Medicine"; this of course allows surgery and also in subjects not taught to unde —for example, medical history—and both su historical theses have in fact been accept universities reserve the right to examine can the subject-matter of their theses, but such an e is rarely required as a routine.

THE M.D. BY EXAMINATION

It could be argued that no doctorate should l merely in recognition of advanced study, and highest academic title should be reserved for have demonstrated their ability to make observations or carry out original research. T be a theoretical argument against the M.D. by tion and would certainly be supported by the the non-medical faculties. Theory and tradit ever, ought not to be allowed to outweigh considerations, and if the M.D. by examinatio useful, or could be made so, it should be contir

The most serious objection to the M.D. by ex is the fact that it is an unsuccessful competito qualifications, such as the M.R.C.P. If the examination were a generally recognised alte the M.R.C.P., it would be unobjectionable—t reason why one type of institution should monopoly of a particular type of qualificatio fact the M.D. by examination and the M.R.C. alternatives. The generally accepted higher tions in clinical medicine are the M.R.C.P. corresponding Scottish and Irish diplomas (incl Glasgow fellowship), and in seeking a higher ap an M.D. in medicine might well be at a dis compared with holders of these diplomas. If in medicine were to be an acceptable alternat various higher medical diplomas, the M.D. r would have to be standardised within narro Similar objections could be made to the M.D. health, a subject in which all practical r adequately met by the D.P.H.

In defence of the M.D. by examination it *argued that its object is not to furnish the* with an officially recognised-certificate but to and reward higher study for its own sake. Tl *is that anyone seeking a higher qualification* i medicine would naturally prefer a certificat

ut the realm and conveying substantial privi-
second defence would be that the M.D.
ions are of a higher standard than membership
ions. It is probable, though not certain, that
e standard is higher—on this point it would be
g to have the opinions of examiners and
s with experience of both types of examination.
ination for the London M.D. in psychological
is officially stated to be of a "distinctly
standard than the examination for the D.P.M.
courses seem to be open to the universities:
ld convert the M.D. by examination into a
qualification acceptable in lieu of the M.R.C.P.
r higher diplomas, or stiffen the requirements,
altogether from the field of specialist certification
shing examinations as an avenue to the M.D.
nd possibility, that of stiffening the require-
ould imply the recognition of two distinct
postgraduate attainment: a lower, marked by
hip and other diplomas, and a higher—for
es of mature experience—marked by the M.D.
ponding course seems to be favoured by some
in connexion with the parallel problem of the
and the Ch.M. degree. Of the three possibilities,
e least desirable and the case against it must be
t length.

eed of postgraduate examinations in medicine
gery and their various special branches will
e questioned; on the other hand, it is extremely
whether two levels of attainment ought to be
d. Preparation for a membership or fellowship
tion entails the prolongation far into adult life
mature attitude to knowledge. Although the
e is acquiring practical experience in his field
ling widely, his reaction to what he reads is
bly different from that of the laboratory worker
rch student. In the main, the examination
e has greater confidence in the printed word
re respect for authority; he runs the risk of
g a pedlar of other men's opinions, and can
gainst it only by obtaining some first-hand
ce of research. The M.R.C.P. or F.R.C.S. who
such experience may throw off any ill effects of
d study, but the medical laboratory worker has
antage of an earlier start. The standard of
ge represented by the M.R.C.P. and F.R.C.S.
be accepted as sufficient for all practical pur-
examinations of still greater difficulty would
scholasticism that would be against the interests
the candidates and of medical science.

ion of the M.D. by examination would represent
in the withdrawal of the universities from the
technology and would be in line with current
ty policy. In this connexion it is interesting to
the possibility of a further differentiation in
between the universities and the medical cor-
s. The Goodenough Committee[1] thought that
tion with regard to postgraduate medical quali-
was unsatisfactory; they concluded that
s requiring university courses—those in public
clinical pathology, bacteriology, and tropical
—should be awarded only by universities, and
ponsibility for all other postgraduate medical
s should be assumed by the Royal Medical
. The Royal College of Surgeons of England
wn a lively interest in technical qualifications in
branches of surgery (including dental surgery);
other hand, the Royal College of Physicians of
seems to confine its interest to general medicine,
h the membership may be granted on published
Clinical medicine is no less diversified than
surgery, and a case could be made out for granting the M.R.C.P. in special branches of medicine—pædiatrics, for example—as well as in general medicine, as at present. The institution of such alternative routes to the M.R.C.P. would facilitate the abolition of the M.D. by examination and would have two further advantages: by allowing the candidate to concentrate on his future specialty it would enable him to reach a higher standard of knowledge; and it would make possible a special examination for research physicians who at present seem obliged to devote an excessive proportion of their time to preparation for the ordinary M.R.C.P.

THE M.D. BY EXAMINATION AND THESIS

There is even less to be said for the M.D. by examination and thesis than for the M.D. by examination alone. The M.D. by examination alone may at least be equivalent to a recognised diploma; it is doubtful whether as much could be said of the examination part of the M.D. by examination and thesis. The chief objection to this method, however, is the distraction of the candidate from his research in order to prepare for the examination. Candidates for higher qualifications are as a rule heavily engaged in some branch of medical work, and the time and energy that they can give to study or research are limited. The preparation of a thesis is likely to absorb all the candidate's leisure for many months at least and should not be done under the shadow of an examination. Furthermore, the prescribed subject of the examination may have no direct bearing on the candidate's line of professional work; it is unreasonable, for example, to require a medical laboratory worker to stand an examination in clinical medicine. The non-clinician is as fully entitled to proceed to the doctorate in his own faculty as the clinician and should not be made to feel that he really ought to seek it elsewhere.

The present compromise of exempting candidates who produce meritorious theses from examination is unsatisfactory, because the candidates must prepare themselves for a possible examination long before the date on which exemption can be granted. If a thesis does not reach the required standard, the proper course is to withhold the degree. The attainments tested by examination and by thesis are very different, and mediocrity in both tests should not be regarded as equivalent to excellence in one of them.

THE M.D. BY THESIS

The preparation of a thesis is a most valuable form of intellectual training. Even though the scientific results may be of no great importance, the writer of a thesis learns many things that will be useful to him throughout his future career. He learns how to find out what has been written on any subject, how to use the *Index Medicus*, and how to obtain reprints, microfilms, and photostatic copies of articles not available locally. He must grasp the essentials of publications in foreign languages and is probably obliged to grapple with statistical methods to interpret his own findings. Through reading and abstracting a large number of papers he learns to read critically, and in presenting his own results he practises the arts of writing, of tabulating data, and of choosing illustrations. The work itself teaches him how hard it is to observe accurately and acquaints him with the common sources of error. If thesis work is a training in discrimination and criticism, it is no less a moral discipline, for scientific work, like other kinds of exploring, needs a stout heart as well as a clear head; once begun, the task cannot honourably be abandoned and *tenax propositi* must be the candidate's watchword, or, if need be, his epitaph.

Supervision by an experienced worker is highly desirable. Without expert guidance, the novice in research is likely to waste much time and to take many wrong turnings. Help of this kind is perfectly legitimate; candidates working in universities or large hospitals should have no difficulty in finding it locally; others may obtain it from professional tutors. Advice is needed at every stage of the work; the candidate who accepts it gracefully and works conscientiously will be a better doctor than he was when he started, for the benefits of thesis work do not depend on the topic investigated, and the greatest of them is not specialised knowledge but an independent mind.

---

[1] nough Committee (1944) Report of Inter-Departmental mittee on Medical Schools. London. Chap. 20.

Every candidate has his own difficulties and these are best dealt with individually by his supervisor. One difficulty—that of writing—is probably common to all and deserves a few words here. The presentation of results is as important as the conduct of the work itself and needs as much study. The man who is well read in general literature will have less trouble than others, but every candidate should study the technique of scientific writing. Textbooks and pamphlets on the subject are available; if studied with care, they will help the candidate to set out his work to the best advantage. The finished work should be read by one or more critics for the detection of obscurity, repetition, mannerisms, and lack of balance—faults that no writer, however experienced, can with certainty detect in his own work.

It is not desirable to restrict the topics of M.D. theses to particular departments of medical knowledge. The existence of separate degrees in medicine, surgery, and obstetrics (in Ireland only) no doubt underlies the opinion that M.D. theses should be on topics either in or closely relevant to clinical medicine. In this connexion it is important to distinguish between two of the several meanings of the words "medicine" and "medical." In a narrow sense they denote the field of work of the British physician and the American internist—namely, clinical medicine as distinct from surgery and obstetrics. In a broad and no less legitimate sense they apply to all branches of science and practice connected with health and disease; they are so used with reference to the profession itself, its education, journals, societies, official bodies, and university faculties. It is in this comprehensive sense that the word "medicine" should be understood in relation to the M.D., and any topic of professional interest to medical men should be admissible as the subject of a thesis—in other words, the M.D. should be the doctorate of the whole faculty.

The division of medicine (in the broad sense) into separate subjects is convenient for teaching, but research work is not always easy to classify. Specialists in different subjects often use the same techniques, and it may be difficult, for example, to say whether a particular thesis is surgical rather than physiological—nor does it matter, provided there are no departmental limitations on the topics permissible for the degree. Physicians and surgeons are nowadays largely concerned with the same problems, and the prohibition of surgical theses cannot be justified on scientific grounds. It may be that the fundamental objection is not to surgery, but to descriptions of surgical technique: if so, descriptions of other kinds of technique should logically be banned. It is, however, unreasonable to assume that the description of a new technique is necessarily less important than a record of work carried out by an established technique; the prohibition of theses dealing with technique is scientifically unsound, and every thesis—technical or non-technical—should be judged on its merits. It is true that surgical theses may count towards the degree of Ch.M., but surgeons who have no desire to take the associated examination should be free to submit a thesis for the M.D.

There is no objection to interviewing a candidate in connexion with his thesis, and universities might well reserve the right to require an interview. This right, however, should be exercised only when the examiners feel unable to reach a decision without further information. In practice, an interview should rarely be needed, and when required should be solely for
questions arising out of the thesis; it shoul
made an occasion for examining candidates in
or special subjects—if it were, it would be op
same objections as procedure by examination

degrees of merit may be justifiably distinguis

It is true that theses are not always easy t
and inevitable that there should be differences
as to their quality. Such differences should n
removable by correspondence between the in
external examiners. The function of the examin
be limited to reporting on the merits of a the
making recommendations regarding distincti
award or non-award of the degree and any
should be a matter for a committee. Experienc

st suitable committee for this purpose would
d of the faculty, which is large enough to
bias on the part of the examiners; an
miner who knows that he may be subjected
g oral examination by his colleagues is likely
his report with great care. A small com-
l be less able to cope with a persuasive and
dvocate—whether for or against the candi-
ge committee often proves especially helpful
grading of a thesis, and the most valuable
s to debates on such questions are often
embers who are entirely detached from the
ndidate, and the examiners.

uld be little difficulty in classifying a thesis
; or as above the average but not first-
vorthy of acceptance—a grading that could
by the award of a gold medal, a commenda-
pass. Where finer distinctions are made—
, by recognising two degrees of commenda-
tion to a gold-medal class—the possibilities
ent are obviously greater.

btful whether M.D. candidates are in fact
y a spirit of pot-hunting; if they are, the
ly to be exorcised by the first few months'
most of them would be only too pleased with
isor's assurance that they have a reasonable
assing. In support of distinctions it can be
t theses undoubtedly differ in quality and
n be graded with a fair degree of accuracy—
t can be recognised, it is difficult to see why
ot be rewarded. Apart from actual awards,
existence of a system of distinctions may
good work and deter candidates from treating
ations as a matter of routine. The objections
o far been made to distinctions are not sub-
ough to warrant any material change in the
awarding them. Minor adjustments might
for example, a simplification of the grades—
sities not awarding distinctions might well
hether they are not depriving their abler
of a legitimate professional advantage.

SUMMARY

irements of the British universities for the
e are described and discussed in the light of
icisms.

). by examination is not serving a clearly
ofessional purpose. It could be made an
to the M.R.C.P. or be granted only for
s of a much higher standard; the best plan,
would be to abolish examinations as an avenue
)., a course that would be facilitated by the
of special branches of medicine as alternatives
medicine for the M.R.C.P.

TEACHING OF PHARMACOLOGY IN THE U.S.A.

DERMOT B. TAYLOR
B.A., M.B., B.A.O. Dubl.
LECTURER IN PHARMACOLOGY, KING'S COLLEGE, UNIVERSITY OF LONDON; TRAVELLING FELLOW, BRITISH POSTGRADUATE MEDICAL FEDERATION OF THE UNIVERSITY

IN 1945, with the aim of improving the design of our own practical pharmacology classes, a study was made of a selection of the teaching methods and materials in use in British medical schools. When, in 1948, I spent a year in America I took the opportunity of making a corresponding study there. The differences between the teaching of pharmacology and therapeutics here and in the U.S.A. were so conspicuous that the scope of the investigations was extended. This brief account cannot convey my deep appreciation of the excellence of American teaching methods. In all or almost all of the schools pharmacology is taught in the second year. A common distribution of the subjects in the curriculum is as follows:

First or freshman year	Second or sophomore year	Third or junior year	Fourth or senior year
Anatomy gross	Pharmacology	Pathology	Pathology
Histology	Pathology	Medicine	Medicine
Nervous system	Bacteriology	Surgery	Surgery
Biochemistry	Medicine	Obstetrics	Obstetrics
Physiology	Surgery	Public health	Public health
Medical psychology	Obstetrics	Pædiatrics Legal medicine	Pædiatrics

The general arrangement of the curriculum is well expressed in the bulletin of information of the College of Physicians and Surgeons of Columbia University. "Beginning in the first two academic years with a study of the basic sciences, particularly anatomy, physiology, biochemistry, bacteriology, pharmacology, and pathology, the student prepares himself for an understanding of the problems to be encountered in his later clinical work. The third and fourth academic years are devoted to mastering the methods of diagnosis and treatment of patients and acquiring a knowledge of disease patterns, emphasising in particular the more important fields of medicine, surgery, pediatrics, obstetrics, and psychiatry."

The teaching of experimental pharmacology is particularly impressive. The experiments are advanced and no expense seems to be spared to provide useful and cogent material to illustrate the principles of the subject. Large numbers of dogs, cats, and rabbits are used in the practical classes. The following list of the experimental animals used per 100 students taught gives some idea of the expenditure.

School	*Dogs*	*Cats*	*Rabbits*
A	83	200	120
B	37	100	160
C	400	50	100
D	140	24	104
E	200	—	64
F	50	—	200
G	150	166	—

The cost of food, maintenance, and purchase of experimental animals for the practical pharmacology class of school A comes to about £3000 per year.

Therapeutics is partly taught separately to pharmacology in that considerable contributions are made by the various specialists on the staffs of the departments of medicine, surgery, &c. The catalogue of one school lists the following departments as participating in the course: internal medicine, pædiatrics, nervous diseases, diseases of the chest, dermatology and syphilology, radiology, general surgery, orthopædics, ophthalmology, otolaryngology, urology, proctology, stomatology, and obstetrics and gynæcology. The large joint clinics were an interesting feature noted at some schools. At these a patient would be presented and the case reviewed and discussed for about an hour and a half by three or four staff members of various interested departments. These clinics were well attended and produced much lively discussion.

In the table the part-time teachers and research fellows and assistants have not been included in calculating either the hours of teaching or the number of medical students per member of the teaching staff. These part-time workers play a useful part in keeping research going while the full-time staff are teaching, preparing classes, and busy with administration. Some of them do a little teaching themselves and their joint efforts often make a valuable contribution to department duties. Figures for technical specialists and assistants were not available. Many of these people have university degrees and all are skilled operators or analysts.

In their report on "The Essentials of an Acceptable Medical School" the House of Delegates of the American Medical Association recommended that "For each 25 students in a class there should be at least one full-time assistant in each of the preclinical departments." The figures show that, with negligible exceptions, all the American departments studied comply with the ment. It is clear that there is a very generous of full-time teaching staff and that this staff backed by part-time staff, research assistants, assistants, and technical specialists. From my limited observations, it appeared that most pharmacology departments either have at l square feet (not including animal rooms) of fl at their disposal or will have it shortly. In no it necessary to run experimental classes more to accommodate all the medical students. In of the departments studied the teaching of basic student pharmacology occupied one term. The with two exceptions, took two terms. In most the total time devoted to pharmacology was of the time devoted to physiology. An American student spends about 5% of his total medical c clock hours at pharmacology. Pharmacology, is a subject of major importance, accorded vi with anatomy, physiology and biochemistry.

I would like to express my indebtedness to many for their kindness and hospitality and also for the and instructive frankness of their discussion and I am especially indebted to Prof. John Fulton Donald H. Barron, whose physiology dep Yale was to me during my stay there an e liberal organisation and leadership that I will remember.

PROS AND CONS

uld the first M.B. examination be taken at school or university? The first two articles printed below express q views on this question which, though not new, has been discussed with fresh rigour during the past few years me of the universities have had relatively more vacancies in the first than the second year—occasionally with the result that a student who has passed the examination from school has studied for it again at the university. In ıd pair of articles two university teachers voice differing opinions on postgraduate qualifications, centring their ıts on the M.R.C.P. examination, which was the subject of a report last month by a committee of the college.

THE FIRST M.B.

discussion of the proper place in which to teach emedical subjects of physics, chemistry, and must first deal with certain fundamental aspects ical training.

ıg the last half-century it has become increasingly hat the system of medical education is tending nd more to produce individuals possessing (at hen appropriately examined) a mass of poorly ted factual data and a steadily diminishing y for critical assessment and broad constructive ng—in brief to inculcate knowledge without ı. It has even been proposed that there should *brands of medical men*: (1) a numerically major trained along strictly vocational, and inevitably c, lines in a technical medical school; and (2) t minority who would receive a university type ning with its implications of broad foundation on l science and development of the critical faculty. roup would presumably form a sort of officer class which alone would be drawn the medical academi- the specialists, and the investigators. With any proposal I disagree completely: nothing would ter calculated to destroy medicine as a profession. alue of the doctor to the community does not ith his care of the individual patient but includes fluence he has on the life and thought of his fellows. rry out this function effectively he has to be an ted person, not merely a technician; he must le to appreciate the habits and behaviour of man ocial animal in relation to his past, his present, and ture: above all, he must have critical powers which nable him to separate the grain of truth from the of specious and meretricious polemics which is the ıt coin of political propaganda. Furthermore, any educational dichotomy presumes the feasibility parating the two groups before the age of twenty: he science of psychological selection is at present ed for this task.

THE NARROW AND THE BROAD

late years vocational instruction has been introl into school education; and the last two years at l are now often devoted to fairly intensive study small group of subjects—for instance, chemistry, cs, and biology—to the detriment of broad cultural ing. This trend has been greatly encouraged by the m of awarding scholarships and—in England but n Scotland—by the possibility of exemption from edical subjects in the university, enabling the ıt student to pass directly to the preclinical subjects ıatomy and physiology.

ıe British Medical Association's admirable report ıedical training[1] expresses in elegant terms profound pproval of this practice. While agreeing completely this viewpoint, I do not believe that there is ısic merit in the conventional classical education, eby the scholar gains a substantial knowledge of ı and Greek to the exclusion of training in science. ly the lessons to be learned from a study of the ics are of two kinds. The first is the intellectual discipline and exercise derived from mastery of a foreign language—valuable training but one that can be equalled by study of a modern language or indeed of any coherent body of factual data. The second and much more important lesson is concerned with insight into the intellect and behaviour of man and with the inculcation by precept and example of the classical qualities of restraint and toleration base on the concept of man as an intellectual and moral animal. In this respect the lesson of the classics is also the lesson of human biology, which in its broadest functional sense is the study of the whole range of adjustments whereby man achieves the equilibrium with his environment which Herbert Spencer has described as the ultimate aim of all biological endeavour. This second advantage of the classical training could equally well be won from a study of English translations of the relevant texts, and the enormous time saved by excluding ancient linguistics could be devoted to an integrated cultural curriculum embracing English language, mathematics, a modern language, and general science including biology. Instruction in history should not be the conventional record of dates and dynasties but the story of mankind in relation to an environment, turbulent both in its purely external material aspect and in its internal moral aspect, as epitomised by endless conflicts of ideologies and "-isms." Such a presentation would at last integrate the useful aspects of the classical tradition into the broad stream of general science.

THE MISSING R

An essential facet of the training should be mathematics. It is astonishing that whereas an intimate knowledge of the mother-tongue is always regarded as an indispensable aim of good education, no such obligation seems to be attached to the language of space and number. An honours degree can be obtained without knowing much more about mathematics than is needed to obtain correct change in the tram. Even among those who have had some mathematical training comparatively few know anything of the laws of chance or the methods of assessing significance and correlation in numerical data. Yet knowledge of this sort is a prerequisite to understanding of the quantitative aspects and trends of populations of measurements, whether they relate to morbidity and mortality or to political economy and sociology.

Some of the conventional content of mathematics as taught to the senior forms could with great cultural advantage be replaced by elementary statistics, the examples for which could be drawn from the biology class. For instance, the method of assessing the significance of the difference of yields of two plots in the school garden seems to me to involve much less intellectual effort on the part of the teacher and the taught than the intricacies of Greek grammar or some of the theorems of solid geometry. At the same time training in statistics is cultural in the widest sense, for it introduces the pupil to some of the fallacies as well as some of the precisions of the quantitative approach to phenomena. A community with a high proportion of people with this knowledge has gained some immunity to the petty and specious misconceptions which mar so much popular belief.

---

e Training of a Doctor: report of the medical curriculum ommittee of the B.M.A. London, 1948. See *Lancet*, 1948, , 839.

I consider that premature specialism in school education has had a most harmful effect, and that a return to a broad cultural programme with little or no vocational bias is a vital necessity. Probably the biggest obstacle to reform is the lack of suitable teachers. Most of those who are already teaching are themselves the victims of premature specialism, and find it difficult to take part in a comprehensive, closely knit, cultural syllabus; indeed they are often imbued with blind devotion to their own subject, a study of which they conceive as the only gateway to educational salvation.

THE DEVELOPING MIND

If the schools are to provide a wide education it will be impossible for them to instruct future medical students in chemistry, physics, and biology up to the standard where university training in these subjects can be obviated. That it now often can be obviated is the clearest proof that schools are failing in their duty to ensure education suitable not only for earning a livelihood but for citizenship.

This practice of giving premedical instruction in schools ignores a most important distinction between school and university training—an inescapable distinction because it is based on differences between the adolescent and the adult mind. Up to the age of 17 or 18 a considerable element of didactic authoritarianism is probably necessary in teaching, since the average young mind finds difficulty in grasping the full implications of the scientific method with its emphasis on accuracy, quantitative observation, the designed experiment, and controls and statistical tests. In science there are no opinions, no ideologies—only facts, measurements, and correlations upon which are based hypotheses with no transcendental merit of their own but depending on the observations they claim to integrate. To instil this attitude is the first and most important duty of university education, and it must remain its exclusive prerogative not for any petty monopolistic reasons but because it is only in an institution where devotion to research and discovery exists on a parity with teaching that such a tradition flourishes. Instruction at university level has another quality which distinguishes it from schoolroom learning—that is, continual emphasis on the unknown. In fact it has been said whimsically that the educational function of a university is to teach what is not known. Engaged equally on research and teaching, the university teacher avoids that element of didactic authoritarianism which, useful as it may be in the schoolroom, stifles inquiry and is the negation of the scientific outlook.

Universities rightly insist that their teachers shall engage, or shall have been engaged, in research, partly because this is a leaven which converts instruction into inspiration and instils love of learning and veneration for truth. Such an outlook is the only sure protection against that didactic materialism and intrusion of political ideology which, under the name of Michurinism, with its denial of the incontrovertible principles of mendelian genetics, threatens the scientific life of the U.S.S.R. and ultimately that of the whole world. Even in the university, chemistry, physics, and biology should not be taught to the medical student as vocational subjects but in common with students destined for other careers.

Thus my contention is that the premedical subjects, while taught at school as part of a broad cultural syllabus, must also be taught at the university and used for instilling the scientific method. Devotion to such an [illegible] against medicine deteriorating [illegible] all that has been achieved in the long struggle to bring science to the aid of clinical practice and to put an end to the mass of medieval empiricism and mysticism which under such as the "art of medicine" or "clinical instinct" patient and doctor alike.

W. MELVILLE ARNOTT

Professor of Medicine, University of Bi

* * *

ANY inquiry into the relative merits of te subjects of the first M.B. examination—namely, chemistry, and elementary biology—at school versity should begin with the question: Of w is instruction in these subjects to the medical st is the place occupied by such instruction at adequately filled?

There are of course good reasons for ret subjects as part of medical education. Anyone spend his life in the field of human biology be acquainted with the elements of these th sciences; and this need would continue eve doctor did not constantly employ the elemen niques of physics, chemistry, and biology in the of his practice. Moreover, it is essential that in clinical training the student should learn to d between facts derived from observation and ex and extensions beyond the facts or conclusions dr them about which it is often necessary to p open mind. Anyone who has engaged in clinical will know how readily "it may be" becomes "i how confused the average student becomes w fronted with a problem whose solution requires a of the objective and scientific judgment w preliminary training should have instilled. the student should understand when he is e inductive, and when deductive, reasoning so tha recognise that which requires further obser experiment before it can be accepted as establish

TEACHING METHODS

Unfortunately medical education today fall deal short of complete success in all of these This is not a matter of curriculum but rather of The perennial discussions which have as the the improvement of medical training have o almost entirely concerned with the number o to be taught and their relation to one another ra with the lecturer's approach to his subject teaching techniques and methods of pre Here is a wide field for observation and exp and the immediate need is for a method by results of different teaching methods can be c All too often the first-year university courses in c physics, and biology, far from instilling a lov respect for, scientific methods of thought, see student to offer a mass of irrelevant and a unrelated facts. Yet there is substance to the that this is because the average student reachin school is ill-equipped to profit by the kind of that should benefit him later, and that in students get the kind of instruction they deser

This implies a defect in the previous edu school; and certainly the student should be into contact with scientific discipline before h the university, so that he may benefit fully from advanced teaching which it should be the busin university to offer. The present first-year class medical faculties are necessarily large, with ha opportunity for individual instruction and g yet to teach scientific habits of thought, and the between inductive and deductive reasoning as w tween experimental facts and conclusions dra them, requires individual instruction, careful su and discussion in small groups. The real purpo instruction at present given in the first yea medical school is not to impart information he student for the study of physiology, bio- -, and anatomy with which medical education)egins.

THE SCHOOLS' RESPONSIBILITY

·eparation, requiring a habit of mind rather ackground of knowledge, should begin early; senior science teachers at schools are best give the necessary individual instruction with ttention to the difficulties of particular students. ruction is already given in the upper forms of hools, where the teaching of science some- :hes a high level; but a large number of schools unable to offer training in medical physics, ·, and biology.

training in science begins with the making of ›servations; from these are drawn conclusions lidity is examined by experiment. In this way ›nt is gradually introduced to the experimental ·; and the results of a number of experiments are l in the construction of a hypothesis, the useful- ·hich can be tested by further experimentation. roach is generally more valuable to the medical in his clinical work than the more common of instruction in the basic sciences of enunciating ·' and then setting the student an experiment proves" it.

points are mentioned in order to underline the ice of the earliest instruction in science and to › the plea for a secure foundation in science ie student faces the problems and readjustments rsity life. The responsibility of preparing the for the first M.B. examination is small compared s task. If the form of the first M.B. examination anged this responsibility could be discharged chools. The student should then arrive better d to undertake the more advanced biological of physiology, biochemistry, and anatomy, dy of which involves not only the continued ion of the scientific discipline, to which he ome accustomed at school, but also detailed anding of the workings of the human body.

THE PRECLINICAL YEARS

ching plan designed to subserve these ends would cessarily contain all the material at present l in the first-year medical course. For example, t not be practicable to include organic chemistry; ng with elementary statistics and genetics, could ided in the early part of the university course, t five terms of which would then be devoted lly to biochemistry, physiology, and anatomy, the sixth term free for the most difficult, and at in many respects the least satisfactory, period— , the introduction to the study of disease.

ie proposal to transfer, in modified form, the ar medical subjects to school education were to pecialisation at an earlier age, it would stand ned; for even today the prospective medical ; is required to specialise too young. In the ts of a more liberal education the medical school, l of its responsibilities for teaching elementary , chemistry, and biology, could introduce a number tive courses into the first year of study. The ty of these should be non-medical—for example, natics, social science, political economy, philo- and psychology. If this conception be correct, ie statement that instruction in physics, chemistry, iology should properly be undertaken only by rs who also prosecute research is somewhat wide mark. The initial stages of medical education, ating in the first M.B. examination, require qualities instructors somewhat different from—though by ans excluding—a capacity for original work.

Only when he has learned to appreciate the scientific method is the student equipped to undertake the study of the more advanced biological sciences, where so much is uncertain and so much unproved. Only by enlisting the coöperation of the schools can more time be obtained for teaching the basic medical sciences, the further study of which is the greatest need in medical education today.

HAROLD SCARBOROUGH
Reader in Medicine, University of Birmingham.

THE MEMBERSHIP

"Education is the development of the reasoning faculty in man and the gift to him of means to use this to the best of his ability."—C. M. BOWRA.[1]

It is customary for teachers to blame their difficulties and failures on their predecessors: the university on the secondary school, and the latter on the elementary school. My own experience leaves me in no doubt that the troubles of postgraduate education are engendered in the curricula of the undergraduate schools. The overburdened undergraduate, coping with over-departmentalised segmentation of medical knowledge, has too often failed to achieve any real mental synthesis. This will never be corrected until we have reoriented the curriculum around Medicine as a science in its own right. "It is not profitable to study theory without some practical experience of the facts to which it relates."[2] Physiological, biological, physical, chemical, pharmacological, and pathological theory must be studied in relation to the problems of medicine itself, interest being roused by demonstration on the patient. This has become our task in the postgraduate period.

It may be objected that medicine, as well as being a science, is an art based on experience of the natural history of disease, and that the direct study of the sick and their symptoms is not necessarily scientific. There is here no hard and fast line of demarcation. The observational faculties of a trained clinician may form the basis of quite secure logical deductions even though the facts are intractable to any form of numerical measurement or graphic registration. The learning of this part of medicine takes a lifetime of experience. With the inevitable progression of modern medicine, however, empiricism gives way continually to science: the deep sighing respiration of Kussmaul is related to the degree of diabetic acidosis, and jaundice without bile in the urine becomes the sequel of hæmolysis. The old and permanently valuable clinical correlation remains, but it is better understood.

The imponderable character of the art renders this part of medicine peculiarly prone to dogma and empirical rules. The nature of our work as clinicians fosters looseness of thought, for we are in the unfortunate position of having to give explanations of many incomprehensible phenomena, if not to students, at least to patients or their relatives. If we are to turn out competent specialists, we must not only ground them well in the art but teach them that progress in understanding can be attained only by the application of meticulous observational and scientific method. Contact with the scientific approach will sharpen the powers of observation of our budding specialist, develop his critical faculties, and enable him to perceive innumerable weaknesses in our systematised "knowledge," even in some of the most hallowed and respectable of our beliefs. In certain instances the young man, so exposed, will take the opportunity to seize the initiative, will demonstrate his own capacity for originality and logical thought, and will be easily marked out as a potential leader.

THE EXAMINATION BURDEN

The principles of postgraduate training of the specialist laid down by the Royal College of Physicians envisage the provision of just such opportunities for the acquisition of scientific discipline. The biggest hindrances, however, in this admirable scheme are postgraduate examinations. While examinations may be a necessary evil in the undergraduate period, a rigid code of formal tests imposed on a developing adult mind may be a serious insult. Boards of examiners have the best of intentions; but, rightly or wrongly, examinations perpetuate the textbook complex of the undergraduate, and put a premium on the often outmoded textbook ideas of yesterday. Young men dare not dwell too deeply on their research interests lest they develop "dangerous ideas" in the eyes of their examiners. Higher qualities of scholarship, capacity for original thought, and special aptitudes in particular branches of medicine handicap rather than help in the higher examinations. Formal examinations are not suited to the questing mind and are more readily passed by those with good memories and simple faith.

Take the converse side of the picture. Success in the membership may prove the practical performance of a young man today but it does not guarantee that his standards will be maintained next year or—more important—a decade hence. So we come back to the necessity of recognition by colleagues of high clinical capacities gained by experience: only in this way can we choose our future specialists. No examination label or diploma can replace this judgment. The positive recognition of excellence is infinitely better than the negative method of excluding those who falter before a monstrous examination barrier.

THE REMEDY

We live in a period of our professional history in which we have slipped our cables from many valued traditions. We should also have the courage to jettison a few that are less worthy, in order to unburden the maturing minds of our young graduates. Abolish the need for *multiple* higher degrees and diplomas. Against the background of the necessary experience accept the demonstration of academic excellence by thesis, by published work, or by discussion before our alert learned societies. Our universities could help by greater uniformity and vigilance over the granting of doctorates, and a successful M.D. by thesis should be an alternative channel to specialism. Let our hospital boards cease the reiterated demand "M.R.C.P. essential," though they might suggest that a higher degree or diploma was desirable. We should get rid of the necessity for special coaching and cram courses: these can never be an educational credit to any country. Study for examinations cramps and harasses excellent young men from our Dominions. Let these men rather acquire method by studying the example of our gifted teachers; let them acquire a philosophy of medicine in our country, where the individual has a dignity higher than in most others; and let them learn technique, outlook, critique, accurate observation, and biological sense from our leaders in medical science. Let them refresh themselves in the living stream of new knowledge and inquiry, and abolish the necessity for stagnation among the backwaters of the outworn knowledge of yesterday.

Our colleges would do well to ponder the words of Dr. Alan Gregg,[3] recently addressed to the American College of Physicians: "A way to raise the general performance of specialists is to exert jealous and vigilant control on behalf of excellence, variety, and freedom to go beyond our present knowledge."

JOHN MCMICHAEL
Professor of Medicine, University of London.

THE MEMBERSHIP

comparisons, if odious, are nevertheless pertinent examiners for a specialist diploma cannot set andard to match the capabilities of a superman. R.C.P. should be within the grasp of any doctor average ability and native wit who is willing to to the discipline of intensive reading and authori- nstruction. This attainment is not to be regarded ething reserved for a specially gifted minority. ploma is a professional high-jump within the ence of most young doctors who are prepared to the necessary sacrifice; but such an athletic ance becomes increasingly difficult with the of the years, and many are too old at thirty.

t the examiners do demand is absolute proficiency knowledge and technique tested in a qualifying ation; and a candidate who is found wanting in eory and practice of such fundamentals must no mercy.

e second place the examiners expect the candidate y his familiarity with physiological mechanisms oducing them naturally and effectively into his ion of the principles of medicine. This require- provides the most searching test of the whole ation, and insistence upon it largely accounts for h prestige of the membership diploma. Far from unfair it sets a premium on orderly thinking and s the coup-de-grâce to those who have not schooled lves in the elementary principles of logic. Unfor- ly many worthy candidates find this hurdle larly difficult. Though well read and highly ent, they suffer from a peculiar form of mental which renders them incapable of mobilising the ation under examination conditions which include xorable time-limit.

and certainly least is a knowledge of rarities. on things most commonly occur, said Samual Gee; is aphorism is never forgotten by examiners who their business. Contrary to popular belief, rare s do *not* occupy a large part of a specialist's g day. He is much more often engaged on unusual stations of common maladies; and he will be ed as a specialist mainly for his capacity to cope these unexpected and puzzling developments. heless in a postgraduate examination it is perfectly ble to test a candidate's knowledge of bizarre mes and clinical oddities. To do so is merely to ate the demands which will occasionally be made im by the general practitioner. As with other of the examination, the importance attached to ind of knowledge is subject to the examiners' ion; and it cannot be doubted that these assessors lways be experienced consultants with a well- ped sense of perspective. The M.R.C.P. examination is conducted with certain general principles in ather than a set of rigid rules, is a flexible instru- designed by and for a very peculiar people.

SELECTING THE COMPETENT

le the M.R.C.P. may set proper standards for those ofess to be specialists, it would be puerile to suggest ossession of this or any other diploma should be ed as the sine-qua-non for advancement in all lised branches of medicine open to the physician. xamination can at best serve to select physicians re professionally competent in the sense that has lescribed; it would be palpably absurd to suggest when a man of five and twenty has obtained this f approval from the college he can claim to be ing but a beginner in a particular branch of the whole subject of medicine. At this stage he may have little more claim to merit than a promising craftsman or an efficient tradesman; many years must elapse before he can acquire the wide clinical experience which he needs—to say nothing of maturity, judgment, shrewdness, insight, tolerance, and many other virtues, not the least valuable of which is a sense of humility.

Happily there are still men and women in the profession of medicine who are a law unto themselves and who make no pretence at conforming to convention unless such action can be justified on first principles. This small minority includes some of our ablest research-workers and teachers, and a heterogeneous group of practitioners who have discovered in medicine a useful introduction to literature or art, religion or philosophy. Some of these, possessing the precious gift of originality, are destined to make important contributions to medicine. To urge such intellectuals to submit to further formal examination is to be guilty of philistinism in a particularly offensive form. Augustine Birrell has adequately commemorated our valued if eccentric brethren:

> "... it must be owned that great creative and inventive genius, the most brilliant gifts of bright fancy, happy expression, and a glorious imagination, well nigh seeming as if it must be inspired, have too often been found most unsuitably lodged in ill-living and scandalous mortals."

STANLEY ALSTEAD

Professor of Materia Medica and Therapeutics,
University of Glasgow.

Reviews of Books

Essentials of Orthopædics

PHILIP WILES, M.S. Lond., F.R.C.S., F.A.C.S., orthopædic surgeon, Middlesex Hospital, London. London: J. & A. Churchill. 1949. Pp. 486. 42*s*.

SECTIONS on orthopædics in the standard surgical textbooks have, with more rigid specialisation, become superficial, and hitherto most orthopædic textbooks have been too abstruse or too compact to be of much use to the struggling student. This eminently readable and well-selected book should prove most useful, for it is simply written, covers a vast amount of bone and joint disease in its well-illustrated chapters, and is authoritative without being dogmatic. Early chapters deal fully with the problems of postural defects, which must surely try the ingenuity of those in general practice; they are so common and so difficult that it is wise to allot a good deal of space to them. Chapters dealing with the deformities and diseases of the various joints follow, and a final relatively short section covers infections, tumours, and diseases of bone and the nervous orthopædic affections. These sections are all most carefully compiled, and little is missing. Since the author has wisely refrained from including traumatology, diseases of bones and joints appear in their true perspective, not lost in a welter of strains, sprains, and breaks. This delightful book will undoubtedly go into further editions.

Anæsthetics for Medical Students

GORDON OSTLERE, M.A., M.B. Camb., D.A., late senior resident anæsthetist, Hill End (St. Bartholomew's) Hospital. London: J. & A. Churchill. 1949. Pp. 108. 7*s*. 6*d*.

THE practice of anæsthesia, like that of surgery, is gradually becoming the province of those who have had special postgraduate training. However, just as the general practitioner will probably always be called on to perform certain simple operations, so will he continue to be called on to administer simple anæsthetics for them. It is clear then that this ability must still be acquired during the medical course. Most of Dr. Ostlere's book deals, as it should, with the practical side of anæsthetics, telling the student in a conversational but lucid manner just what premedication to give, how to administer the common anæsthetics in a simple way, how to keep a good airway, and how to avoid or treat the more common troubles that arise during the administration. He is evidently an enthusiastic teacher and he can hardly inevitably, less efficiently than before. Many are earning appreciably less. Instead of encouraging the growth of partnership practice, the Act has made it increasingly difficult and unprofitable for a doctor to take an extra partner. Payment by level (and not over-generous) capitation fee with a permitted maximum of 4000 patients does little to encourage a doctor to keep his list small enough for careful, vigilant, and unhurried service to his patients; nor does it secure any effective recruitment to the under-doctored areas. True, the general practitioners have themselves suggested an increase in the remuneration to be paid for the first 1000 patients on a principal's list in the hope that this will make small lists less of a liability and provide better partnership prospects. But the implementation of this proposal hangs upon securing extra millions from a reluctant Government; and even should this be secured, if doctors are to be redistributed really effectively there will still be need for progressive reductions in the permitted maxima on lists to a figure much nearer three than four thousand patients. Without these reforms we are in danger of accepting standards of practice lower than those we know are needed.

The negotiation of amendments of this sort is a matter for discussion between the Government and the doctors. But there is another side to the question of recruitment to general practice that concerns the profession alone. The general practitioner sometimes feels that he is regarded as the Cinderella of the profession, not only by medical students but *also—only too obviously—by consultants* in the teaching hospitals. It is a strange anomaly that despite the large proportion of medical students who eventually enter general practice, their education and inspiration during the most receptive and formative years is left almost exclusively to men who have themselves never been in general practice and have little understanding of its needs and difficulties. Who can be surprised that the student does not often gain a true appreciation of the opportunities and satisfactions which general practice can offer, nor sometimes even the training which will best fit him for his eventual vocation? In a memorandum of evidence[2] submitted in 1943 to the Goodenough Committee, the British Medical Association said:

> "Complaint is frequently made by general practitioners that they did not receive as students the knowledge that they later found to be essential in their daily practice. It is said for example, that teaching given in children's illnesses, nutrition and dietetics, infectious diseases, and psychoneuroses is often quite inadequate. In some schools the student is not given the opportunity of mastering the technique of such surgical procedures as a general practitioner may properly be called upon to undertake. . . . The Association suggests that medical education would be assisted if suitable general practitioners were invited to advise on and be associated with the training of the student. Medical faculties or medical school committees might with advantage include one or more general practitioners in their membership. The function of these practitioners would be to advise on the curriculum so far as it related to subjects of particular importance in general practice and to ensure that adequate attention was given to them . . . . In the actual teaching general practitioners could render valuable help."

Very few medical schools have so far
steps to implement this policy, but t
emphasis rightly laid on social and en
factors in the production of ill health h
revival of the suggestion that the experie

ae and family, insecurity or anxiety, worry or e on the health of the individual. Above all d inculcate appreciation that the patient is a case but a person and a member of a a consideration that is instinctively in the loctor's mind, shaping his own background ely accounting for his value to the community. his point of vantage in the university, the r of general practice would exert an influence denied to the general practitioner. Such an e, permeating and reorientating the student vould help to bring a new dignity to general , and ensure for the country a steady stream ors well prepared and well satisfied to enter practice.

The New Bacteriology

stream of knowledge is no man-made canal but a brook whose long quiet pools are divided l and sparkling stickles. So it is that methods action in medicine pass from teacher to teacher o change beyond some new facts, some new ks, and sometimes a new illustration. Change, t comes, springs from one man who risks he conservatism of students and the wrath miners. MALL raised anatomy from a slut narnel house and married her to physiology; e nest of fledgings fostered by ELLIOT SMITH ver Street has perpetuated her respectability. ictum by VIRCHOW changed the teaching of ogy throughout the world—not entirely, per- o its ultimate benefit. It was the principles than the practice of medicine which led OSLER e the wisest of all textbooks. These are signal , and they would be more numerous were it : the common and proper caution in experiment expense of others. Pedagogy, like therapeutics, eld for hasty empiricism. Thus special interest es to the proposals for the reform of bacterio- teaching made by Prof. ROBERT CRUICKSHANK inaugural address on succeeding to the chair teriology at St. Mary's Hospital.[1]

re must classify the sciences, bacteriology is a n of botany and the physician does no more than parts of this science which bear on the cause and of disease. But since much of our knowledge ndamental bacteriology arose from inquiry into ems of human disease, the teaching of this subject, e practical class at any rate, has retained a ical aspect. Bacteria are so long and so broad; metabolise this or that; a staphylococcus in clumps and a streptococcus in chains; move (*pace* PIJPER) by waggling flagella. A f the kings of Judah would be more useful in al practice. True, the student learns to stain ercle bacillus; but we are convinced that few uments are used less often in the surgery than a scope, and it is probably better so. The matic lecture will, of course, mention such ical topics as the Schick test; but to most ents this remains a procedure whose use is ed to medical officers of health and whose description is popular with examiners. The teacher of ology cannot overlook the effects of bacterial tion, and cunning mnemonics remind the forgetful of the distinction between a tuberculous and a typhoid ulcer of the bowel. That the student does not emerge on the world ignorant of all the gifts to mankind of PASTEUR and KOCH is due to those who teach him medicine and surgery, and, above all, to the long-suffering superintendent of the hospital where he "does his fevers."

Before he came to St. Mary's, Professor CRUICKSHANK was director of the Central Public Health Laboratory; and like others who have tried to put their knowledge of bacteriology at the service of their fellow doctors, he is unhappy at the prevailing ignorance of the applications of bacteriology to medicine and surgery. The laboratory has functions besides the examination of sputum for tubercle bacilli, and there are reasons other than fear of "missing a dip." for swabbing the throat of the patient with tonsillitis. Technical advances give more and more assistance in the diagnosis of infectious disease and the detection of their origin. Through a variety of causes, originating as much in financial stringency as in specialised knowledge, the very treatment of some infections now falls within the ambit of the bacteriologist. So it is that Professor CRUICKSHANK's views have a strong practical bias, and his suggested course might fairly be called "bacteriology as applied to medicine." We think that the chief importance of his suggestion lies, not in any omissions, but in a dissection of the subject as it now stands and the assignment of the parts to their logical places in the curriculum. The botanical aspects, morphology and physiology, he would promote to the first year of study with the rest of botany; surely among the smaller forms of life the student might learn as much about an anthrax bacillus as about a slipper animalcule? He suggests that the next occasion on which the student should meet bacteria would be in general pathology. The relation of host and parasite is a subject stimulating to teacher and pupil, and it is taught today exceptionally well; inflammation, immunity, and allergy are the algebra of infectious disease, and the closer these are linked with the reaction of the organism to the rest of its environment the better. But Professor CRUICKSHANK is probably right in assuming that the next step—the relation of the parasite to the community—is hardly taught at all. To the practitioner immunity must be a matter of rule-of-thumb with a bias in the direction of safety. Yet the spread of disease and the means of limiting it are problems of every daily round. Prophylactic chemotherapy, the danger of nasal carriers of streptococci, the "sterility" of water in the operating-theatre—these are everyday matters far more important than the thirty-nine causes of an enlarged spleen. There is real need for a course in preventive medicine along these lines; and, more than most subjects, it lends itself to practical illustration. Bacteriological technique as usually taught is of the least importance, but mutual tuberculin testing and cultures from the canteen crockery will profitably relieve the tedium of the professorial voice. If any subject must be sacrificed to make room for this, we would suggest the lectures now designated "hygiene": bills of mortality and hoppers, short or long, have little place in the busy doctor's thoughts. Lastly, the place of bacteriology in the diagnosis and treatment of disease must somehow be integrated in clinical teaching. In some textbooks the sections on, say, the diagnosis of typhoid fever suggest that this improvement is overdue. Nevertheless the patient is still a sick person, and it is no part of the bacteriologist's duties to usurp the functions of the physician. Laboratory findings, like X rays, are no more than specialised physical signs, and the absorption of such aids to diagnosis into the curriculum involves every department of a medical school.

---

[1] *St. Mary's Hosp. Gaz.* 1949, 55, 35.

We doubt whether Professor CRUICKSHANK will claim any great originality for these views. Similar opinions have for some years been common gossip among those who teach bacteriology, but it was high time that they were put on paper clearly and publicly. We foresee three main grounds of objection. First, there is a feeling that the unashamed abandonment of "pure science" in favour of its applications is a sacrifice to Mammon. Yet we do not believe that imperfect knowledge of the bacterial capsule is more reprehensible in the physician than ignorance of radiological optics; the medical education is a technical one in which all possible use should be made of the scientific method, but this should not preclude the gleaning of useful information from any credible source. The second objection may well be that the newly qualified student will know no bacteriology. But this is a science that has passed far beyond the standard of the M.B. examination, and he who would spend his days as a gram-stained wretch will be the better for his house-appointments and the serious study of bacteriology as a postgraduate subject. "The examiners" summarises the last objection, which is one that has been raised to every change in methods of teaching. The examiner's first care is to ensure that the successful candidate is fit to practise medicine; if he does not know how to immunise a child against diphtheria he had better wait for three months.

Status of Pharmacology

In no period of medical history has knowledge of drugs advanced so rapidly as in the last quarter century; and the present phenomenal rate of progress shows no sign of abating. One result of the enormous increase in the potent drugs available to the physician has been a healthy tendency to regard diagnosis no longer as an end in itself but as the necessary preliminary to treatment. But there is some danger of a new therapeutic nihilism arising from disappointment or even disaster following the use of these newer remedies. All active drugs may be either ineffective or dangerous if incorrectly used, and the fine new weapons which science has given us can often become lethal in the hands of the ignorant. Pharmacological principles must be thoroughly understood if the modern drugs are to be applied rationally and effectively and if the results of therapy and the claims made for new drugs are to be intelligently assessed. Practical therapeutics, which involves much more than the use of drugs, must be taught mainly by the clinician at the bedside, but the teaching of pharmacotherapeutics will fail if it is not superimposed on a sound knowledge of modern pharmacology. It is the function of the pharmacologist to provide this basic knowledge. A medical man will be learning the use of drugs all his life but the pharmacological laboratory affords him his only formal opportunity to essential facts concerning the actions and of action of drugs and the principles them, and such knowledge becomes more every year.

England is behind most other leading co the attention given to pharmacology in the curriculum and in the staffing and facilities it by most universities. In Germany and the States it has long enjoyed independent sta extensive and well-equipped institutes—on page Dr. DERMOT TAYLOR shows how generou provisions for pharmacological teaching in universities. In England teaching and r pharmacology have too often been regarded activities of the physiology department and i to autonomy have been stoutly resisted, c physiologists. In the last few years, however, outside London has been rapid. By the of the forthcoming session all but one of the provincial university medical schools will independent department and chair in phar or in pharmacology and therapeutics, thus these schools into line, after many years, Scottish universities. London itself is slow to pharmacology as a major subject. There chairs of pharmacology in the university, one of these, at University College, is in a de training medical students. In only three of nine preclinical schools is the pharmacolog ment independent. In one of the remaining included in the department of therapeutics, five it is still a subdepartment of physiolog representation on the academic board of the school. Some recent appointments to re have been a step in the right direction. Bu ships are not enough. If young men are to b aged to take up pharmacology as a car professorial appointments should be made delay. The University of London should whether the time has now come to found chai schools where the work and ability of the pre of the department warrants it; to separate cology entirely from physiology in thos where this has not yet been done; and to a policy whereby, at the end of, say, a five-ye pharmacology in all the London schools w equality of status with the other medical sc

The present scarcity of pharmacologists hinder these developments, for recruitme subject will be encouraged by an increas senior posts—in fact, this is the only way the growing competitive demand for pharm Industry alone would gladly absorb more whole present supply of trained men. N difficulties of accommodation stand in Apart from minimum space requirements for the accommodation for teaching can usually with other departments pending the pro independent teaching laboratories.

More time as well as better facilities are if the medical student is to acquire the safe of knowledge which will prevent him from danger to the community. Time should be cutting out the obsolete, the obsolescent, unduly recondite in other subjects and in p logy itself. It is human pharmacology that nce to the medical student, and it is doubtful extensive practical courses involving complex experiments, such as are in favour in the States, would give him an appreciation of cological facts and principles commensurate eir cost in effort and money. Much of the of such courses can be more effectively dealt demonstrations. Many of the basic principles action, and much of the detail and of the methodology of pharmacology can and should trated by experiments on man and will then interest of the student as animal experi- seldom do. In research, too, there is much to e in human pharmacology and in applying to quantitative methods which have proved their n general pharmacology and for the develop- of which British pharmacologists were largely sible. This is work for which medical schools uliarly suited. Where man is the chief object ly pharmacology is likely to be taught as a immediately applicable to him and to the ns of practical medicine, the pharmacologist e clinician will meet on an equal footing, and ration in teaching and in research will become der of the day. This desirable state of affairs ome about exceptionally in spite of difficulties, cannot become general until pharmacology is the status it now deserves.

TOO MANY COURSES ?

ER the end of the war the needs of medical officers ilised from the Forces were met mainly by the offer ss-1 hospital posts for those going into general e and of class-3 posts for those aiming to become tants. But there was a considerable demand e the regular demobilisation scheme for post- ate instruction which would help in obtaining l diplomas in such subjects as public health, rial health, radiology, and anæsthetics. Unfortun- the controversy over the new health scheme bred minds of many the idea that they must at all avoid entering general practice; the possession of oma seemed a passport to a specialist or consultant Candidates for the higher diplomas of M.R.C.P. or S. came principally from those holding class-3 posts istrars, whose numbers had been greatly swollen by eation of "supernumerary" posts. Many, however ot desire a hospital post and believed that a diploma ne specialty could be obtained with less effort and d an easier way of escape. An officer who expressed ire to work for a diploma in radiology was offered ss-1 post and was almost automatically promoted ss 3 after six months even though his knowledge of es might be meagre. A course in public health did equire residence, and a substantial grant could be ned from the Ministry of Labour.

iversities responded to the demand by establishing postgraduate courses or reviving those that had in abeyance during the war; for the session 1948–49 70 special courses were offered in fourteen university es. These universities are now faced with a con- able drop in the number of applicants. The future ublic health and industrial health is obscure and at not financially attractive, while in other e immediate post-war vacancies have been and the number of future appointments on ital staffs, though uncertain, is likely to be less than anticipated. Thus the number of candidates for omas is returning to normal and represents those are genuinely keen on this type of work. Clearly the number of postgraduate courses is in excess of demand. For some courses there have been no applicants, while for others only four or five students have entered. A glance at the list of special courses on p. 391 reveals their multiplicity. A good case could be made out for concentrating instruction by common agreement in a few centres that have special resources such as whole-time teachers. University authorities are apt to view with disfavour postgraduate courses that do not pay their way: but they may be reluctant to give up such postgraduate teaching, which they naturally wish to provide for their past students, who in turn find it less expensive to attend courses near their homes. But the multiplication of courses also causes great waste of time and energy. Instruction for one diploma may require the services of five or six lecturers, who are disheartened when, after much preparation, they meet a class of only a few students. The problem is more acute in provincial universities than in London, where there are postgraduate schools and institutes separate from the undergraduate teaching schools and where numerous attractions can be found for the hours of leisure.

The large and efficient provincial medical schools, with their rich clinical material, facilities for research, great preclinical departments, and close contact with the science faculties, may well decide that their real place and finest work in the postgraduate field is in training and encouraging students of promise who have been selected as trainee consultants. The whole-time clinical professors and their colleagues have very great responsibilities in providing the consultants of the future, and, through their contacts with the other hospitals in their regions, maintaining the highest standards of practice and research. Except in some selected centres with whole-time staffs or special institutes, instruction for certain diplomas (the diploma in clinical pathology is a good example) and refresher courses for general practitioners might well be left, under the guidance of the university directors of graduate studies, to the large so-called non-teaching hospitals, whose staffs have already shown themselves keen and competent to undertake postgraduate training of this sort.

B.C.G. FOR STUDENTS AND NURSES

TWO years ago the Tuberculosis Association, acting with the Joint Tuberculosis Council and the National Association for the Prevention of Tuberculosis, submitted a memorandum[1] to the Minister of Health appealing for a trial of B.C.G. vaccination on selected groups. This suggestion was accepted, and a letter lately received from the Ministry (and the Department of Health for Scotland) by hospital authorities suggests that action will not be delayed much longer. In Norway, which with other Scandinavian countries has done much of the work on which the case for B.C.G. rests, compulsory vaccination of certain groups has been willingly accepted.[2] Here vaccination is to be voluntary, those who refuse it being considered as controls. The Ministry proposes that the vaccine—which is to be imported from Denmark—should first be offered to medical students and nurses who are found to be negative to a tuberculin (preferably Mantoux) test. Specialists will be able to obtain supplies for individual contacts with known cases of tuberculosis, and others exposed to special risk, but the general public are not yet included in the scheme. Elsewhere the vaccine devised by Calmette and Guérin has been used extensively for twenty-five years, and its more impatient advocates will find sardonic amusement in the Ministry's statement that "no certain claims can yet be made for this form of immunisation under conditions here, but it is now considered to warrant trial."

Points of View

THE DOCTOR'S PROFESSION*

4. Medical Education

If the previous argument holds, it is clear that the education which the doctor receives is of the utmost importance and ought to be more adequate in at least two directions. First, the medical student needs a much clearer understanding of his task in relation to the general life of society around him than he has ever had in the past. Secondly, he should be helped to obtain some criteria by which to make judgments upon the ethical problems which confront him in his work, some training in how to handle and direct responsibly the increasing powers over life and death which are placed in his hands, and, above all, an approach to his studies which makes him begin by considering patients *not as laboratory specimens but as living individuals.*

THE SOCIAL OUTLOOK

The first need is increasingly widely recognised today. The development of the study of social medicine and the prolonged discussion of the establishment of a State medical service have both prompted the medical profession to think more seriously than ever before about its relation to society. At the same time, this new awareness is not yet very clearly reflected in the method of medical training. The strong recommendations of the Goodenough report[1] on the subject of social medicine, like those of previous official reports to which it refers, are still more in the nature of pious aspirations than of definite proposals which have an immediate prospect of being implemented. Such a situation is perhaps inevitable in a large and ill-defined field, and there are many encouraging signs of developing interest in the subject which will find expression in curricula before very long. What is more alarming, however, is the superficial nature as yet of so many social medical studies. While the careful and thorough researches of such workers as Prof. John Ryle of Oxford are a notable exception, social medicine as it is made available to students is still too often little more than a series of obvious generalisations culled from textbooks of popular science, geography, and sociology. Much of the suspicion doctors have of social medicine as a subject may be partly due to their philistine conservatism; but it is also partly due to a recognition that it has not yet succeeded in being much more than a means of recording what public-health work and ordinary social observation have already taken for granted. Much greater emphasis needs to be laid upon the fact that, because society and the medical profession are both living organisms, the profession's conception of its task in society should never become static. The natural tendency of the student is to assume that his task as a doctor will be the same as that of the generation before him. This tendency is strengthened by the fact that it is the honorary physician or surgeon with a large private practice who is the dominant teaching influence in the medical school. It can be kept in proportion only if a clear understanding of the changing social function of medicine affects the teaching of the whole school.

INSULATED STUDIES

It is, however, when the second set of needs is considered that the deficiencies of existing medical education become most manifest. Formal medical edu still almost entirely technical in character. It that the student may learn a great deal about the patient relationship from observation of his chi visits his patients in the wards. This practice *is such a distinctive feature of English* medical of teaching medicine at the bedside, is in itself ad The unconscious educational influence of sharin on-going life of a great institution like a teaching must also be very considerable. Whether th unreceptive type of student learns anything fro however, is left entirely to chance; and, excep rare instances where the teacher is a man of out quality, what even the good student learns is be unsystematic and undigested. We have grave dangers to which the conception of the merely as technician leads. Does present-day education do enough to help the doctor to anything but a technician?

Most medical schools are part of universit medicine is rightly proud of its title as a lear fession. The Goodenough report asserts boldly:

> "By its nature and standard the training shoul the student with a university education on broad a lines. A mere technical training will not fit a st perform his future professional work properly. have a university education if he is to enter practice with an outlook beyond the confines of a nation syllabus, with a well-disciplined mind, wid interests and an intelligence able to move with the of human knowledge."

As the report itself recognises, however, to mere title of university education to what the receives in the medical school is itself no g that these desirable gifts will be obtained. T human interests and the intelligence which is *develop with the development of knowledge* in it sidedness come only if the student is in personal both with teachers who try to see their subj the round," in relation to other branches of and to fundamental human interests, and wi students who are pursuing quite different stud similar spirit. Most medical schools are insulat by geography, as in London, or by pressure as in most other places in Britain, from effective *with other faculties of the universities of which* part. The result is that few of them know a genuine university quality. The other faculties th suffer from being over-specialised and technical approach, and often have little to offer the student in the way of a synoptic viewpoint ov he is in effective contact with them. If the to be more than a technician and to become a re person in the use of his skill, it can be done o conscious effort—an effort which involves ch the nature of medical education itself, change must be linked to a new conception of u education as a whole.[2]

THE MATERIALISTIC BIAS

For example, one of the greatest difficultie way of a medical education lies in the natur subjects studied. The nature of scientific m *such that it not only gives those who use it*—r beliefs they may formally possess—a practical favour of what is commonly termed materiali also it constantly encourages them to lose sigh distinctive nature of human personality itself mystery can never be adequately analysed by categories alone. The educational discipline of experience itself, as well as the influence of out life derived from other sources, may frequently ct this tendency, which in the nature of the evitable, and, if properly handled, need not be . Its proper handling, however, involves that ent should be warned against the dangers of n of outlook to which his continual preoccupation entific studies lays him open. Unless he strives eract these dangers he will run the risk of being doctor, because it is those aspects of human ities that are imponderable from the scientific view which are sometimes of greatest importance xercise of the healing art.

[1] Report of [illegible] London, 1944.

[2] See Sir Walter Moberly, *The Crisis in the University.* for the Christian Frontier Council, by the S.C. London. 1949. 15s.

uld be remembered also that if the temptations ical materialism are counteracted for the doctor fact that he necessarily has a great deal of experience and is constantly dealing with people ents of crisis in their lives, they are made more y other circumstances peculiar to the doctor's lot. ctor, like other scientific students, is brought at ressionable age into an atmosphere dominated scientific attitude, which has many virtues ry great prestige and which appears to produce ore impressive proof of its validity by its magnifi- sults. But his position is made peculiar to some by the fact that, both in the medical school erwards in practice, his life is quite exceptionally He has little time to reflect upon his experience, the only criteria he has received from medical ion for judging human experience are those ed by the scientific attitude it is not surprising e tends either to discuss all matters affecting life and destiny in terms of the narrow philosophy r among scientists, or, more commonly, to ignore ompletely in the practical atheism of an extremely xistence. It may be added that it is the testimony ny medical men that the necessity of treating t bodies with cold objectivity in post mortems perations also encourages them in a certain insen- y and lack of imagination which first arise as a e mechanism against violent assaults on their s but which often harden into habits of mind. doctors testify to the importance of this last in their own experience.

SPIRITUAL ILLITERATES

s makes the doctor ill-disposed to examine the or otherwise of the Christian faith, and makes nclined to prejudge the issue one way or the other, thrusting it aside as irrelevant or holding it in a er unrelated to his scientific experience. As one r puts it:

> A man who is a Christian must have studied and lerstood Christianity. That is to say, he must know nething of the Bible, and he must understand what is ant by the many difficult and sometimes misleading ms used. Little is left of either time or energy, from life of the science student or worker, for reflection on, study of, these things. Scientific study, induces a found 'failure of conception.' From his unfamiliarity h religious concepts, the scientist comes to have the st fantastic ideas about what Christians mean by, for ample, 'God,' or 'prayer.' It is little wonder that he uses to believe in them."[3]

is a fact of grave concern to Christians, but it should f concern to others also, because it means that this ession, which holds such great powers in its hands, a constant danger of being imperfectly educated ss it makes strenuous efforts to overcome the erfection of the very discipline which it has itself eloped in recent times as a means of education.
